KEYWORDS: plasmepsin, Malaria, protease, peptidomimetic, PEXEL, trafficking.

#### Abstract

Plasmepsin V is an aspartyl protease that plays a critical role in the export of proteins bearing the Plasmodium export element (PEXEL) motif ( $\mathrm{RxLxQ} / \mathrm{E} / \mathrm{D}$ ) to the infected host erythrocyte, and thus the survival of the malaria parasite. Previously, development of transition state PEXEL mimetic inhibitors of plasmepsin $V$ have primarily focused on demonstrating the importance of the $\mathrm{P}_{3} \mathrm{Arg}$ and $\mathrm{P}_{1}$ Leu in binding affinity and selectivity. Here, we investigate the importance of the $\mathrm{P}_{2}$ position by incorporating both natural and non-natural amino acids into this position and show disubstituted beta-carbon amino acids convey the greatest potency. Consequently, we show analogues with either cyclohexylglycine or phenylglycine in the $\mathrm{P}_{2}$ position are the most potent inhibitors of plasmepsin V that impair processing of the PEXEL motif in exported proteins resulting in death of $P$. falciparum asexual stage parasites.

## INTRODUCTION

The World Health Organization estimates that around 3.5 billion people, about half of the world's population, live at risk of malaria [1]. Malaria is caused by Plasmodium parasites and results in approximately 460,000 deaths annually [1]. $P$. falciparum and $P$. vivax are the most virulent species, accounting for $75 \%$ and $20 \%$ of cases worldwide, respectively. There is currently a strong commitment to eliminate malaria in the 21st century. However, the current arsenal of clinically used artemisinin combination therapies and drug candidates undergoing clinical assessment may not be sufficient to eliminate the disease, due to the threat of emerging drug resistance [2, 3]. Thus, new agents are required that target multiple stages of the malaria parasite's lifecycle with novel mechanisms of action.

Genome sequencing uncovered the $P$. falciparum parasite expresses ten cathepsin D-like or A1 family aspartyl proteases, known as plasmepsins (PMs). The PMs have diverse roles across the parasite's lifecycle and several essential PMs are considered attractive antimalarial drug targets. PMs I, II, IV and histo-aspartyl protease (HAP) are localised to the digestive vacuole of the asexual parasite and degrade hemoglobin providing sustenance for the parasite [4, 5], but genetic studies have established these PMs are not essential for parasite survival [5-9] and thus not viable antimalarial targets. PMs VI-VIII are not expressed in the asexual stage of the parasite, but PMVI and PMVIII have undefined but essential roles in $P$. berghei within the mosquito stage [10, 11], while PMVII is not essential in P. berghei [12]. The role of PMs VI, VII and VIII in species that infect humans is not known and thus additional evidence is required to confirm their validity as drug targets. PMIX has an indispensable role in invasion and PMX is essential for both invasion and egress of the erythrocyte and both are considered potential antimalarial drug targets [13, 14].

Several PMs have been targeted with small molecules with varying degrees of success[13-22], but none have progressed to the clinic.

An important feature of malaria parasite survival is the remodeling of the host erythrocyte environment. A key event that underpins the remodeling process is the transport of many hundreds of parasite proteins into the erythrocyte [23-25]. Exported proteins play critical roles in parasite survival, such as providing sustenance for the parasite to replicate, evasion of the host immune system and nutrient and waste efflux from the host erythrocyte [26]. Approximately 460 proteins destined for export possess an $N$-terminal motif with the consensus sequence $\operatorname{RxLxQ} / E / D$, known as the Plasmodium export element (PEXEL) [27], or vacuolar targeting sequences (VTS) [28]. For proteins to be exported, the endoplasmic reticulum resident aspartyl protease, PMV processes the PEXEL motif at the C-terminal amide bond of leucine [29, 30]. The processing event is an essential step in the export of PEXEL containing-proteins [23, 29-32] and for export of PEXEL-negative proteins because the latter require PEXEL proteins for their trafficking for the survival of the malaria parasite in erythrocyte [23, 26, 33]. PMV and PEXEL proteins are highly conserved in all Plasmodium species including the most virulent species, P. falciparum [25].
Previous work

Figure 1. The structures of WEHI-916 1 and WEHI-842 2 shown occupying substrate binding pockets of PMV, and the relationship to the work undertaken here focusing on the $\mathrm{P}_{2}$ region.

Recently, it was shown transition state peptidomimetics that mimic the native PEXEL motif, RxL, are potent inhibitors of both $P$. vivax and $P$. falciparum PMV. The earliest example, WEHI9161 (Fig 1) [34, 35], was shown to prevent processing and export of PEXEL containing proteins resulting in death of $P$. falciparum asexual stage parasites in vitro. A subsequent study established that replacing the $\mathrm{P}_{3}$ Arg in 1 with canavanine (Cav) produced the analogue named WEHI-842 2 [36, 37], (Fig 1) which possessed a 10 -fold improvement in affinity for PMV and for killing $P$. falciparum compared to $\mathbf{1}$. An X-ray structure of $\mathbf{2}$ bound to PMV was also obtained and illustrated key binding interactions that described the requirement of the RxL motif for binding to PMV [37].

These studies further corroborated biological evidence that PMV plays a vital role in protein export and that this process is essential for parasite survival, thus reinforcing PMV as a promising antimalarial target.

The critical nature of the $P_{3} A r g$ and $P_{1}$ Leu in the PEXEL motif has been well studied [23, 29, 30, 34-36, 38, 39] (Fig 5), but the importance of the $\mathrm{P}_{2}$ region remains largely unknown. The limited studies describing the $\mathrm{P}_{2}$ region show that both Val (seen in $\mathbf{1}$ and 2, Fig 1) and Ile appear optimal, while analogues that possess a $\mathrm{P}_{2}$ Ala, Phe or Leu have lower affinity for PMV [34]. This and unpublished data from our laboratory led to the hypothesis that peptidomimetics that harbor a $\mathrm{P}_{2}$ amino acid with di-substitution at the beta-carbon (Fig 1) have greater affinity for PMV than those analogues without this substitution pattern.

Herein, we explore the $\mathrm{P}_{2}$ region by way of substituting both natural and non-natural amino acids into the RxL mimetic scaffold. The amino acids selected for integration of the $\mathrm{P}_{2}$ position would test our hypothesis that beta di-substitution is important for improving PMV potency. Thus, amino acids such as cyclopentylglycine, phenylglycine were selected, but also amino acids that did not possess beta di-substitution to serve as controls, such as phenylalanine and norvaline. There were several other factors that influenced our choice of amino acid for the $\mathrm{P}_{2}$ motif. The first was the selection of amino acids that possessed hydrophobic side chains because the $S_{2}$ binding cavity is mostly lined with hydrophobic amino acids, as shown in the X-ray structure of $\mathbf{2}$ bound to PMV (Fig 2). Hydrophobic amino acids were also chosen to increase overall lipophilicity of peptidomimetic analogues to assist in membrane permeability. Lastly, there was an emphasis on selecting non-natural and non-essential amino acids, as it was reasoned that these amino acids may impart greater metabolic stability, given they would not be readily recognized by other proteases compared to the 20 proteinogenic amino acids.

Figure 2. The $S_{2}$ substrate binding cavity of PMV (grey surface and blue amino acids) occupied by the $\mathrm{P}_{2} i \operatorname{Pr}$ group of WEHI-842 2 (green). The image was created using the X-ray structure of $\mathbf{2}$ bound to P. vivax PMV (PDB: 4ZL4).[37] Hydrogen bonds between 2 and PMV are highlighted with yellow-dotted lines.

Previous studies have shown the incorporation of Cav into the $\mathrm{P}_{3}$ position of PEXEL mimetics are 10 -fold more potent than the Arg orthologue (see $\mathbf{1}$ versus $\mathbf{2}$ in Table 1 for comparison) [36, 37]. However, due to the ease of access and availability of Arg compared with Cav, we first
incorporated Arg into all $\mathrm{P}_{2}$ analogues. We then proposed to integrate Cav into the $\mathrm{P}_{3}$ position of the analogues that possess the greatest affinity for PMV. In earlier studies [34, 36], the N-terminal Cbz and C-terminal $\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}$ functionalities, seen in 2 (Fig 1 and 5), were shown to be optimal, and thus would remain the same for the analogues produced in the present study.

## RESULTS AND DISCUSSION

## Chemistry

Exploration of the $\mathrm{P}_{2}$ site begun with the synthesis of analogues. We used solution phase peptide synthesis following established procedures in literature [34, 36, 39] to construct analogues (Scheme 1). Briefly, the synthesis started with coupling the commercially available Boc-protected amino acid 3 with the $\mathrm{NH}_{2}-\mathrm{Sta}(S, S)-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}$ to produce dipeptide 4 . We found that directly accessing the tripeptide $\mathbf{6}$ by coupling $\mathrm{Cbz}-\mathrm{Arg}(N, N-\mathrm{diBoc})-\mathrm{OH}$ to the Boc de-protected dipeptide 4, was low yielding. To circumvent this issue, the dipeptide $\mathbf{4}$ were Boc deprotected and coupled to $\mathrm{Cbz}-\mathrm{Orn}(N-\mathrm{Boc})-\mathrm{OH}$ to give the tripeptide 5 . The $\operatorname{Orn}(N-\mathrm{Boc})$ functionality on $\mathbf{5}$ was then transformed to $\operatorname{Arg}(N, N-d i B o c)$ over two steps to yield the tripeptide 6. At this stage, Cbz-Cav( $N-$ $\mathrm{Boc})-\mathrm{OH}$ was also introduced, by coupling to the Boc deprotected dipeptide 4 to produce the Cav analogue 7. Finally, the Boc groups were removed from 6 and 7. However, in this deprotection we discovered a trifluoroacetamide byproduct. The trifluoroacetamide byproduct has been reported with similar chemistries in the past [40, 41], but it was unknown mechanistically why this byproduct was observed in this instance. To overcome this issue, we removed the trifluoroacetamide group using $\mathrm{K}_{2} \mathrm{CO}_{3}$ in MeOH , then TFA was applied to give the TFA salts of the tripeptide products $\mathbf{8 - 2 8}$.

For $\mathrm{R}^{2}$ refer to Table 1.

## Structure and activity relationship

To assess the effect that the $\mathrm{P}_{2}$ modifications have on PMV activity, compounds $\mathbf{8 - 2 8}$ were evaluated using the previously described fluorogenic assay format [36]. Briefly, compounds were assessed for their ability to block cleavage of a fluorogenic peptide containing the RTLAQ PEXEL
sequence of the exported protein KAHRP (Knob-associated histidine-rich protein) [42] by recombinant $P$. vivax PMV [37]. We have included benchmark compounds $\mathbf{1}$ and $\mathbf{2}$ for comparison of assay performance in this study compared to that in previous studies [34-36, 39]. Of note, analogue $\mathbf{1 1}$ that possesses an $i \mathrm{Pr}$ in the $\mathrm{P}_{2}$ position has similar activity to the previously described $\mathbf{1}[34,35]$ in this assay format. The results of the PMV assay are summarized in Table 1.

The results of the PMV assay show that small aliphatic substituents in the $\mathrm{P}_{2}$ position, such as Me , Et and $n \operatorname{Pr}(\mathbf{9 - 1 1})$, have increasing modest affinity for PMV ( $\mathrm{IC}_{50} 7.2,0.51$, and $0.12 \mu \mathrm{M}$ respectively). Compounds with larger aliphatic substituents, such as $i \mathrm{Pr}, i \mathrm{Bu}, s \mathrm{Bu}$ and $\mathrm{CH}(\mathrm{Et})_{2}$ (11-13 and 15) have improved potencies ( $\mathrm{IC}_{50} 0.12,0.17,0.03$ and $0.11 \mu \mathrm{M}$ respectively) compared with the smaller substituents. Notably, analogues that harbor beta-disubstitution, such as $i \mathrm{Pr}, s \mathrm{Bu}$ and $\mathrm{CH}(\mathrm{Et})_{2}(\mathbf{1 1}, \mathbf{1 3}$ and 15) are more active than $n \mathrm{Pr}$ and $i \mathrm{Bu}(\mathbf{1 1}$ and 12) arguably supporting the hypothesis that beta-disubstitution is important for PMV potency. Further supporting this notion, $s \mathrm{Bu}, \mathrm{CyPen}, \mathrm{CyHex}$ and $\mathrm{Ph}(13,16-18)$ in the $\mathrm{P}_{2}$ position were found to be the most potent analogues in this study ( $\mathrm{IC}_{50} 0.026,0.055,0.024$ and $0.029 \mu \mathrm{M}$ respectively). Analogue 14 with a $t \mathrm{Bu}$ at the $\mathrm{P}_{2}$ position, was not well tolerated $\left(\mathrm{IC}_{50} 6.7 \mu \mathrm{M}\right)$. It is possible that the extra steric bulk at the beta-carbon was not accommodated by the $\mathrm{S}_{2}$ binding pocket of PMV.

Analogue 19, supporting a benzyl group in the $\mathrm{P}_{2}$ position, displayed modest activity against PMV (IC50 $3.1 \mu \mathrm{M}$ ) compared to analogues $\mathbf{9 - 1 3}$ and $\mathbf{1 5 - 1 7}$ with aliphatic $\mathrm{P}_{2}$ groups (all with IC50s $<0.6 \mu \mathrm{M})$. In this instance, disubstitution at the beta-carbon of benzyl-like analogues 20, 21 and 26, did not improve potency ( $\mathrm{IC}_{50}>10,>10$ and $6.6 \mu \mathrm{M}$ respectively) compared to the benzyl analogue $19\left(\mathrm{IC}_{50} 3.1 \mu \mathrm{M}\right)$. It is noted that the stereochemistry of the beta-methyl (L-erythro configured) and hydroxy (D,L-threo configured) may have impacted the PMV activity of compounds 21 and 26, respectively. The exception was 22, which possesses a 2-indane at the $\mathrm{P}_{2}$ site, that was more potent than the benzyl analogue 19 (IC50 0.66 versus $3.1 \mu \mathrm{M}$ ). The difference in activity between the beta methyl benzyl (21) and the 2-indane (22) is likely due to restricted rotation of the phenyl ring of the 2-indane moiety that conferred a more favorable orientation for binding to the $S_{2}$ pocket of PMV.

Compounds 23-26 that possess a hydroxyl at the beta-carbon of the $\mathrm{P}_{2}$ position displayed weak activity against PMV (all with $\mathrm{IC}_{50 \mathrm{~s}}>2 \mu \mathrm{M}$ ). For example, analogues 23 and 24 that possess $\mathrm{CH}_{2} \mathrm{OH}$ (Ser) and $\mathrm{CH}(\mathrm{OH}) \mathrm{Me}(\mathrm{Thr})$ in the $\mathrm{P}_{2}$ position, $\left(\mathrm{IC}_{50}>10\right.$ and $\left.3 \mu \mathrm{M}\right)$ compared to analogues 9 and 11, that have Et and $i \operatorname{Pr}$ aliphatic groups of similar steric bulk ( $\mathrm{IC}_{50} 0.55$ and $0.11 \mu \mathrm{M}$ ). It was reasoned that the modest PMV activity of the beta-hydroxy analogues 23-26 is due to the relatively hydrophobic nature of amino acids that line the $S_{2}$ pocket of PMV (Fig 2).

By examining which functionalities in the $\mathrm{P}_{2}$ position imparted the greatest potency against PMV, we identified that $s \mathrm{Bu}, \mathrm{CyHex}$ and $\mathrm{Ph}(13,17$ and 18) were most optimal. We next studied the effect of replacing the Arg in the $\mathrm{P}_{3}$ position of $\mathbf{1 3}, 17$ and $\mathbf{1 8}$ with Cav. Previous studies have shown that 2, which possesses a $\mathrm{P}_{3} \mathrm{Cav}$, is 10 -fold more potent than $\mathbf{1}$ that has a $\mathrm{P}_{3} \mathrm{Arg}$ (Fig 1) [36, 37]. Our data here confirms this observation, with IC 50 values of 0.119 and $0.019 \mu \mathrm{M}$ for $\mathbf{1}$ and 2 respectively (Table 1). Two analogues, 27-28 with Cav at the $\mathrm{P}_{3}$ position and CyHex , and Ph at the $\mathrm{P}_{2}$ sites were generated and showed a 6 to 8 -fold improvement in PMV potency (IC50 0.005 and $0.003 \mu \mathrm{M}$ ) compared with the $\mathrm{P}_{3}$ Arg comparator analogues 17 and 18 (IC50 0.029 and $0.024 \mu \mathrm{M})$. This supports the previous observations that Cav significantly enhances PMV inhibitory activity compared with analogues possessing Arg at the $\mathrm{P}_{3}$ position. The potency difference between the $s \mathrm{Bu}$ analogues $\mathbf{1 3}$ and $\mathbf{2 9}$ was only 2 -fold and was not as significant as observed with other Cav and Arg analogues, such as $\mathbf{1}$ and 2. Compound $\mathbf{1 3}$ was the most potent $P_{3}$ Arg analogue, but the fold improvement in potency between $\mathbf{1 3}$ and the $P_{3}$ Cav analogue 29 was not as significant as the fold change between other $\mathrm{P}_{3} \mathrm{Arg}$ and $\mathrm{P}_{3} \mathrm{Cav}$ orthologues, for example the 10 -fold improvement between $\mathbf{1}$ and $\mathbf{2}$. As a result, we concentrated on using the $\mathrm{S}_{2} \mathrm{CyHex}$ and Ph analogues, 17, 18, 27 and 28 in further biological and structural analyses.

To examine whether lipophilicity was a contributing factor in the increase of analogue potency, lipophilic efficiency (LipE) was calculated (Table 1). From these calculations, it is observed that even though cLogP generally increases with PMV potency, the LipE values also increase, indicating the improvement in potency observed (for example, from analogue $\mathbf{8}(\mathrm{Me})$ to $\mathbf{1 8}(\mathrm{Ph})$ with respective LipE values of 3.65 and 4.88), is not solely due to the overall increase in hydrophobicity.

## Structural Basis of PMV inhibition

To understand the structural basis for the inhibition of PMV by the analogues, we obtained an X-ray crystal structure of 27 (WEHI-601) bound to PMV (PDB: 6C4G). The structure obtained at a resolution of $2.6 \AA$ was almost identical to the previous X-ray structure (4ZL4) of $\mathbf{2}$ bound to PMV [37]. One notable difference between the structures was the presence of N -glycosylated Asn280 and Asn355 (Fig S1 and S2), a result of using SF21 insect cells to express the protein. Nglycosylation of Asn355 was thought to have occurred in 4ZL4, but poorly defined density in this region of the crystal structure prevented building in the N -glycosylation with confidence [37]. Another difference was the perturbation of the helix-turn-helix motif, compared to 4ZL4 (Fig S1). The X-ray structure also showed that $\mathbf{2 7}$ bound to the substrate binding cleft of PMV in a similar conformation and possessing the same hydrogen bond interactions found with 2 in 4ZL4 (Fig S3). Compared to the $\mathrm{P}_{2} i \operatorname{Pr}$ group of $\mathbf{2}$, the $\mathrm{P}_{2}$ CyHex of $\mathbf{2 7}$ almost completely occupied the $\mathrm{S}_{2}$ pocket of PMV (Fig 3). This occupancy may explain the increase in potency of 27 compared with 2 (Fig 2 and Table 1).

Figure 3. The X-ray structure of $P$. vivax PMV bound to 27 (WEHI-601) (PDB: 6C4G). Shown is the $\mathrm{S}_{2}$ substrate binding cavity of PMV (orange surface and blue amino acids) occupied by the $\mathrm{P}_{2}$ CyHex group of 27 (stick and mesh in magenta).

To further explore the relationship between the structure and PMV activity of analogues we performed docking studies. In the docking studies, the X-ray crystal structure of 2 bound to PMV[37] was used as a template to dock analogues $\mathbf{8 - 2 6}$. The results are shown in Fig S4-7. In general, the docking studies support the PMV assay data, in that the hydrophobic $\mathrm{S}_{2}$ pocket is optimally occupied by either a $\mathrm{P}_{2}$ CyHex and $\mathrm{Ph}\left(\mathbf{1 7}\right.$ and 18). The docking of $\mathrm{P}_{2} \mathrm{CyHex} \mathbf{1 7}$ was
supported by the X-ray structure of the CyHex of 27 occupying the $\mathrm{S}_{2}$ pocket of PMV. It was found that smaller $\mathrm{P}_{2}$ substituents, such $\mathrm{Me}, \mathrm{Et}, \mathrm{Pr}, i \mathrm{Pr}$, don't fully occupy the $\mathrm{S}_{2}$ cavity and are accordingly less active than $\mathbf{1 7}$ and 18 . The modest activity of $\mathbf{1 9}$, can be attributed to the steric size of its $\mathrm{P}_{2}$ benzyl substituent that cannot be accommodated by the $\mathrm{S}_{2}$ pocket, and thus is forced to orientate into solvent space. Docking also provides a possible explanation for why betadisubstitution is important for PMV binding affinity. Firstly, the substitution pattern appears to restrict rotation of substitution at the beta-carbon that is optimal for binding, and secondly, provides the steric capacity to fully occupy the $S_{2}$ of PMV, thus providing a possible explanation why analogues without the beta-disubstitution pattern are generally less active.

## Activity of analogues in $P$. falciparum parasites and human cells in vitro

To establish whether analogues 17, 18, $\mathbf{2 7}$ and $\mathbf{2 8}$ directly inhibit PMV in $P$. falciparum parasites in vitro, we assessed their ability to impair the processing of the exported protein $P$. falciparum erythrocyte membrane protein 3 fused to green fluorescent protein (PfEMP3-GFP). Using previously described protocols [29, 35], we treated the $P$. falciparum parasite line expressing PfEMP3-GFP with compounds 17, 27 (Fig S10), 18, and 28 (Fig 4), and used an anti-GFP antibody to determine the processing pattern of PfEMP3-GFP by western blot. This showed that the $\mathrm{P}_{3} \mathrm{Cav}$ analogues 27 and 28 cause accumulation of uncleaved PfEMP3-GFP to a greater extent than the $P_{3}$ Arg orthologues 17 and 18. Furthermore, 27 and blocked PfEMP3-GFP processing more than 2, consistent with these compounds inhibiting recombinant PMV more potently than $\mathbf{2}$ (Table 1). Thus, the trends in potency seen against recombinant PMV correlate well with the degree of PEXEL cleavage inhibition observed in the P. falciparum-infected erythrocyte PfEMP3 processing assay.

Figure 4. Inhibition of PEXEL processing by selected $\mathrm{P}_{2}$ analogues in erythrocytes infected with P. falciparum 3D7 expressing PfEMP3-GFP. A) Infected erythrocytes were treated with compounds 18, 28 and 2[37] at the indicated concentration, $21(20 \mu \mathrm{M})$ or vehicle control (DMSO). Processing of the PEXEL in PfEMP3 was assessed by immunoblotting with anti-GFP antibodies. Uncleaved (black arrow), PEXEL-cleaved (red arrow), and 'GFP only' (a degraded remnant of the GFP reporter in the food vacuole) species of PfEMP3-GFP are indicated next to the immunoblot and schematically represented in panel C. PEXEL R to A mutant PfEMP3-GFP was included as a size control, and the blot was probed with parasite anti-HSP70 as a loading control. B) Densitometry of the uncleaved band in each lane from A) is shown. The experiment was repeated three times and a single representative is shown. C) Schematic of the GFP protein and its cleavage positions.

We next assessed whether there was a correlation between potency against parasite and recombinant PMV and P. falciparum viability using an assay platform described previously [44]. Briefly, $P$. falciparum infected human erythrocytes were incubated with compounds for 72 h and parasite viability was then determined as a measure of LDH activity (monitored by the consumption of NADH). The results are summarized in Table 1. The P. falciparum viability data show a strong correlation with the PMV inhibitory activity, in that the analogues that possess the greatest inhibitory activity, against recombinant PMV and in P. falciparum PEXEL cleavage assays, are the most potent in reducing parasite viability. For example, $\mathrm{P}_{3} \mathrm{Arg}$ analogues $\mathbf{8}, \mathbf{1 4}, \mathbf{1 9}$ 21 and 23-26 that possess PMV IC ${ }_{50}$ values greater than $1 \mu \mathrm{M}$ don't exhibit parasite activity at the highest concentration tested, while $\mathrm{P}_{3} \operatorname{Arg}$ analogues $13, \mathbf{1 7}$ and $\mathbf{1 8}$ are the most potent against PMV and exhibit the greatest anti-parasitic activity ( $\mathrm{EC}_{50} 1.0,1.2$ and $1.8 \mu \mathrm{M}$ ). The data also shows that the $\mathrm{P}_{3} \mathrm{Cav}$ analogues $\mathbf{2 7 - 2 9}$ are between 10 - and 25 -fold more potent ( $\mathrm{EC}_{50} 91,68$ and 182 nM ) than the comparator $\mathrm{P}_{3} \operatorname{Arg}$ analogues $\mathbf{1 7}, \mathbf{1 8}$ and $\mathbf{1 3}\left(\mathrm{EC}_{50} 1.2,1.8\right.$ and $1.0 \mu \mathrm{M}$ ), which is consistent with activity observed in literature between $\mathbf{1}$ and 2 ( $\mathrm{EC}_{50} 4.0 \mu \mathrm{M}$ versus $0.43 \mu \mathrm{M}$ respectively) (Fig 1 and Table 1) [36, 37]. Furthermore, 27 and 28 are 5- to 6 -fold more potent ( $\mathrm{EC}_{50} 0.09$ and $0.07 \mu \mathrm{M}$ ) at killing P. falciparum parasite than our previously most potent compound, 2 ( $\mathrm{EC}_{50} 0.43 \mu \mathrm{M}$ ).

To assess whether the activity observed in the $P$. falciparum parasite assay was specific to the parasite and not broadly cytotoxic to human cells, we assessed each analogue in a HepG2 cell growth inhibition assay. In this assay, we used Cell Titer-Glo as a metabolic marker of cell growth following previously described protocols [44]. The results of this assay show that only compounds 17, 21 and 22 exhibit growth inhibition ( $\mathrm{EC}_{50} 37,35$ and $24 \mu \mathrm{M}$ ) at the highest concentration tested (Table 1). This activity was deemed to be promiscuous, given there was no observable relationship
between the activities of compounds in the parasite and the cell growth inhibition assay. Notably, analogues $\mathbf{2 7}$ and $\mathbf{2 8}$ that possess the most potent anti-parasitic activity, were inactive at the highest concentration against HepG2 cells, demonstrating that these compounds are not broadly cytotoxic.

Figure 5. Overview of the structure activity relationship of the peptidomimetic inhibitors of PMV from past studies (referenced in the figure) and the study here. ${ }^{\text {a }}$

## CONCLUSIONS

In summary of the work presented here, we have explored the $\mathrm{P}_{2}$ region using the scaffold of pre-existing peptidomimetic inhibitors of PMV (1 and $\mathbf{2}$ ) as a template and demonstrated that the $P_{2}$ region is sensitive to change but is accepting of a larger range of functionalities. This is compared to the $\mathrm{P}_{3}$ and $\mathrm{P}_{1}$ region which only tolerates $\mathrm{Arg} / \mathrm{Cav}$ or Leu in the respective positions (Fig 5) [34-36], thus, reinforcing the exquisite substrate selectivity profile of PMV that has been previously reported [23]. Commonly, Ala, Phe, Thr and Ser are found in the $\mathrm{P}_{2}$ position of native PEXEL motifs of proteins known to be exported [27]. Interestingly, here we show these amino acids are not well tolerated in the $\mathrm{P}_{2}$ position of peptidomimetics, in the context of the current scaffold. A possible explanation for this observation is that maybe the longer native peptide
substrates have a higher affinity for PMV as they engage with $\mathrm{P}_{5}, \mathrm{P}_{4}, \mathrm{~S}_{1}{ }^{\prime}, \mathrm{S}_{2}{ }^{\prime}$ and $\mathrm{S}_{3}{ }^{\prime}$ sites that the peptidomimetics in this study do not, thus compensating for the tolerance of amino acids at the $\mathrm{P}_{2}$ position of the PEXEL in native substrates.

The SAR of the analogues shown here suggests amino acids in the $\mathrm{P}_{2}$ position that harbor disubstitution at the beta-carbon generally have the highest affinity for PMV than those without this configuration. To support this hypothesis, we found that $s \mathrm{Bu} 13, \mathrm{CyHex} 17$ and Ph 18 in the $\mathrm{P}_{2}$ position were the most optimal. This is likely due to their steric occupancy of the $\mathrm{S}_{2}$ cavity of PMV and this was supported by the crystal structure of $\mathbf{2 7}$ bound to PMV. We also show that $\mathrm{P}_{3}$ Cav orthologues 27 and 28 were several-fold more potent against PMV compared to $P_{3}$ Arg orthologues $\mathbf{1 7}$ and 18. Curiously, although $\mathbf{1 3}$ was the most potent $\mathrm{P}_{3}$ Arg analogue, the $\mathrm{P}_{3} \mathrm{Cav}$ orthologue 29 was only 2-fold more potent, and hence analogues with CyHex and Ph in the $\mathrm{P}_{2}$ position were the focus of further biological and structural studies. Compounds 27 and $\mathbf{2 8}$ were also shown to have greater efficacy in preventing processing of the PEXEL containing protein PfEMP3 and reducing the viability of P. falciparum asexual stage parasites in vitro, than any PMV inhibitor previously reported. In conclusion, we have shown the modification of $\mathrm{P}_{2}$ position has led to potent inhibitors of PMV, and thus this work will serve as a template for the future development of PMV inhibitors with improved drug-like properties with the aim to enhance in vitro parasite potency, and potentially efficacy in in vivo models of malaria.

## EXPERIMENTAL SECTION

## Chemistry Experimental

## General

Solvents were obtained commercially and used without further purification. Analytical thin-layer chromatography was performed on Merck silica gel ${ }^{60} \mathrm{~F}_{254}$ aluminum-backed plates and were visualized by fluorescence quenching under UV light or by $\mathrm{KMnO}_{4}$ staining. Chromatography was performed with silica gel 60 (particle size $0.040-0.063 \mu \mathrm{~m}$ ) using an automated purification system. NMR spectra were recorded on a Bruker Avance DRX 300 or an Agilent MR400 400 MHz or an Agilent DD2 500 MHz at 298 K unless otherwise specified. Chemical shifts are reported in ppm on the $\delta$ scale and referenced to the appropriate solvent peak. MeOD and $\mathrm{CDCl}_{3}$ contain $\mathrm{H}_{2} \mathrm{O}$.

LCMS were recorded either on a Waters LCMS system composed of a Waters 3100 Mass Detector, Waters 2996 Diode Array Detector, Waters 2545 Binary Pump, Waters SFO System Fluidics Organizer and a Waters 2767 Sample Manager (Method A), or an Agilent LCMS system composed of an Agilent G6120B Mass Detector, 1260 Infinity G1312B Binary pump, 1260 Infinity G1367E HiPALS autosampler and 1260 Infinity G4212B Diode Array Detector (Method B). Conditions for LCMS Method A were as follows, column: Kinetex TM XB-C18 $5 \mu \mathrm{~m} 4.6 \mathrm{x}$ 50 mm , injection volume $10 \mu \mathrm{~L}, 5-100 \%$ B over 3 min (solvent A: water $0.1 \%$ formic acid; solvent B: $\operatorname{AcCN} 0.1 \%$ formic acid), flow rate: $1.5 \mathrm{~mL} / \mathrm{min}$, detection: $100-600 \mathrm{~nm}$, acquisition time: 6 min. Conditions for LCMS Method B were as follows, column: Poroshell 120 EC-C18, 2.1 x 50 mm 2.7 Micron at $20^{\circ} \mathrm{C}$, injection volume $2 \mu \mathrm{~L}$, gradient: $5-100 \% \mathrm{~B}$ over 3 min (solvent A : water $0.1 \%$ formic acid; solvent B : AcCN $0.1 \%$ formic acid), flow rate: $0.8 \mathrm{~mL} / \mathrm{min}$, detection: 254 nm , acquisition time: 5 min . HPLC conditions used to assess purity of final compounds were as follows, column: Phenomenex Gemini C18, $2.0 \times 50 \mathrm{~mm}$; injection volume $20 \mu \mathrm{~L}$; gradient: 0 $100 \%$ Buffer B over 6 min (buffer A: $0.1 \%$ formic acid in autoclaved MilliQ water; buffer B: $0.1 \%$
formic acid in $100 \%$ acetonitrile), flow rate: $1.0 \mathrm{~mL} / \mathrm{min}$, detection: 214 or 224 nm . Unless otherwise noted, all compounds were found to be $>95 \%$ pure by this method.

HRMS were acquired by Jason Dang at the Monash Institute of Pharmaceutical Sciences Spectrometry Facility using an Agilent 1290 infinity 6224 TOF LCMS. Column used was RRHT $2.1 \times 50 \mathrm{~mm} 1.8 \mu \mathrm{~m} \mathrm{C} 18$. Gradient was applied over the 5 min with the flow rate of $0.5 \mathrm{~mL} / \mathrm{min}$. For MS: Gas temperature was $325^{\circ} \mathrm{C}$; drying gas $11 \mathrm{~L} / \mathrm{min}$; nebulizer 45 psig and the fragmentor 125 V .
$\mathrm{HCl} . \mathrm{NH}_{2}-\mathrm{Sta}-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}, \quad \mathrm{Cbz}-\mathrm{Orn}(\mathrm{N}-\mathrm{Boc})$-Ala-OEt, Boc-Val-Sta-NH(CH2$)_{2} \mathrm{Ph}, \quad \mathrm{Cbz}-$ $\operatorname{Cav}(N-B o c)-O H$ were synthesised using previously described protocols [36, 37]. All other amino acid building blocks were purchased from commercial vendors. All amino acid derivatives are Lconfigured unless otherwise stated.

## Synthesis

## General Procedure D

Cbz-Arg-Val-Sta-NH(CH2) $\mathbf{2}_{2}$ Ph.TFA (11). A mixture of $\mathrm{Cbz}-\operatorname{Arg}(N, N$-diBoc)-Val-Sta$\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(68)(44 \mathrm{mg}, 0.050 \mathrm{mmol})$, in a mixture of TFA $(0.5 \mathrm{~mL})$ and $\mathrm{DCM}(0.5 \mathrm{~mL})$ was allowed to stir for 18 h at $20^{\circ} \mathrm{C}$. The reaction mixture was concentrated to dryness in vacuo. The crude material was dissolved in $1: 1 \mathrm{MeOH}: \mathrm{H}_{2} \mathrm{O}(10 \mathrm{~mL})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(100 \mathrm{mg}, 0.724 \mathrm{mmol})$ was added. The reaction mixture was stirred for 1 h at $20^{\circ} \mathrm{C}$. MeOH was removed in vacuo and extracted into EtOAc ( $3 \times 15 \mathrm{~mL}$ ). The organic layers were combined and washed with water ( 20 mL ) and brine ( 20 mL ), dried with $\mathrm{MgSO}_{4}$ and evaporated to dryness in vacuo to give a residue. The residue was dissolved in 1:9 MeOH:TFA ( 5 mL ) and the solution evaporated to dryness in vacuo to give Cbz-Arg-Val-Sta-NH(CH2)2 $\mathrm{Ph}(11)(9 \mathrm{mg}, 26 \%) .{ }^{1} \mathrm{H}-\mathrm{NMR}(300 \mathrm{MHz} ; \mathrm{MeOD}$, rotamers): $\delta 7.40-7.17(\mathrm{~m}, 10 \mathrm{H}), 5.33(\mathrm{~s}, 1 \mathrm{H}), 5.12(\mathrm{~m}, 2 \mathrm{H}), 4.25-4.12(\mathrm{~m}, 2 \mathrm{H}), 4.00-3.93(\mathrm{~m}, 1 \mathrm{H})$,

## General Procedure A

Boc-Leu-Sta-NH(CH2)2 $\mathbf{P h}$ (30). A mixture of $\mathrm{HCl} \cdot \mathrm{NH}_{2}-\mathrm{Sta}-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(50 \mathrm{mg}, 0.158 \mathrm{mmol})$, Boc-Leu-OH ( $35 \mathrm{mg}, 0.151 \mathrm{mmol}$ ), HBTU ( $75 \mathrm{mg}, 0.196 \mathrm{mmol}$ ) and DIPEA ( $194 \mu \mathrm{~L}, 1.11 \mathrm{mmol}$ ) in DMF ( 2 mL ) was allowed to stir for 18 h at $20^{\circ} \mathrm{C}$. The reaction mixture was quenched with $10 \%$ citric acid solution ( $1 \times 10 \mathrm{~mL}$ ) and the desired product extracted into EtOAc ( $3 \times 15 \mathrm{~mL}$ ). The organic layers were combined, washed with saturated $\mathrm{NaHCO}_{3}(1 \times 20 \mathrm{~mL})$ and brine (1 x 20
mL ), dried with $\mathrm{MgSO}_{4}$ and concentrated in vacuo to obtain the crude residue. The crude residue was purified using a silica chromatography gradient eluting from $100 \% \mathrm{DCM}$ to $10 \% \mathrm{MeOH} / \mathrm{DCM}$ to obtain Boc-Leu-NH( $\left.\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(\mathbf{3 0})(46 \mathrm{mg}, 59 \%) .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(500 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right.$, rotamers): $\delta 7.32(\mathrm{t}, J=7.4 \mathrm{~Hz}, 2 \mathrm{H}), 7.26-7.20(\mathrm{~m}, 3 \mathrm{H}), 6.67-6.52(\mathrm{~m}, 1 \mathrm{H}), 6.38-6.32(\mathrm{~m}, 1 \mathrm{H}), 4.79(\mathrm{~s}, 1 \mathrm{H})$, 4.03-3.97 (m, 2H), 3.84-3.78 (m, 1H), 3.62-3.55 (m, 1H), 3.55-3.48 (m, 1H), 2.87-2.83 (m, 2H), 2.55-2.47 (m, 1H), $2.21(\mathrm{~d}, J=13.9 \mathrm{~Hz}, 1 \mathrm{H}), 1.71-1.54(\mathrm{~m}, 5 \mathrm{H}), 1.44(\mathrm{~s}, 9 \mathrm{H}), 1.38-1.25(\mathrm{~m}, 2 \mathrm{H})$, $0.96(\mathrm{dd}, J=8.6$ and $6.3 \mathrm{~Hz}, 6 \mathrm{H}), 0.90(\mathrm{t}, J=6.6 \mathrm{~Hz}, 6 \mathrm{H}) . \mathrm{MS}(\operatorname{Method} \mathrm{B}), m / z=492[\mathrm{M}+\mathrm{H}]^{+}$. Boc-Abu-Sta-NH(CH2 $)_{2} \mathbf{P h}$ (31). General procedure A was followed using Boc-Abu-OH ( 46 mg , 0.224 mmol ) and $\mathrm{HCl} . \mathrm{NH}_{2}-\mathrm{Sta-NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(50 \mathrm{mg}, 0.159 \mathrm{mmol})$ to obtain Boc-Abu$\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(\mathbf{3 1})(53 \mathrm{mg}, 66 \%) .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(300 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right.$, rotamers): $\delta 7.33-7.19(\mathrm{~m}, 5 \mathrm{H})$, 6.77 (br s, 1H), 6.53-6.49 (m, 1H), 5.10-5.08 (m, 1H), 4.00-3.85 (m, 3H), 3.55-3.44 (m, 2H), 2.83 $(\mathrm{t}, J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 2.38-2.22(\mathrm{~m}, 2 \mathrm{H}), 1.87-1.56(\mathrm{~m}, 4 \mathrm{H}), 1.43(\mathrm{~s}, 9 \mathrm{H}$, overlap with adjacent multiplet) 1.41-1.23(m, 11H), $0.97(\mathrm{t}, J=7.4 \mathrm{~Hz}, 3 \mathrm{H}), 0.90(\mathrm{~d}, J=5.2 \mathrm{~Hz}, 6 \mathrm{H})$. $\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(\mathbf{4 5})$ as a solid $(57 \mathrm{mg}, 75 \%) .{ }^{1} \mathrm{H}-\mathrm{NMR}\left(300 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right.$, rotamers): $\delta 7.34-7.27$ $(\mathrm{m}, 2 \mathrm{H}), 7.26-7.17(\mathrm{~m}, 3 \mathrm{H}), 6.72(\mathrm{~d}, J=9.7 \mathrm{~Hz}, 1 \mathrm{H}), 6.41-6.33(\mathrm{~m}, 1 \mathrm{H}), 5.53(\mathrm{~d}, J=7.9 \mathrm{~Hz}, 1 \mathrm{H})$ $4.47(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 4.36-4.20(\mathrm{~m}, 1 \mathrm{H}), 4.08-3.94(\mathrm{~m}, 2 \mathrm{H}), 3.94-3.81(\mathrm{~m}, 1 \mathrm{H}), 3.64-3.35(\mathrm{~m}, 3 \mathrm{H}), 2.81$ (t, $J=7.2 \mathrm{~Hz}, 2 \mathrm{H}), 2.43-2.27(\mathrm{~m}, 1 \mathrm{H}), 2.28-2.16(\mathrm{~m}, 1 \mathrm{H}), 1.98(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 1.67-1.49(\mathrm{~m}, 1 \mathrm{H})$, $1.45(\mathrm{~s}, 9 \mathrm{H}), 1.24-1.40(\mathrm{~m}, 1 \mathrm{H}), 1.24-1.16(\mathrm{~m}, 3 \mathrm{H}), 0.92-0.86(\mathrm{~m}, 6 \mathrm{H}) . \mathrm{MS}($ Method B), $m / z=$ $480[\mathrm{M}+\mathrm{H}]^{+}$.

Boc-D,L-threo- $\boldsymbol{\beta}$-phenyl-Ser-Sta-NH( $\left.\mathbf{C H}_{2}\right)_{2} \mathbf{P h}$ (47). General procedure A was followed using Boc-D,L-threo- $\beta$-phenyl-Ser-OH ( $49 \mathrm{mg}, 0.175 \mathrm{mmol}$ ) and $\mathrm{HCl} \cdot \mathrm{NH}_{2}-\mathrm{Sta}-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(55 \mathrm{mg}$, 0.175 mmol ) to obtain Boc-threo- $\beta$-phenyl-Ser-Sta-NH(CH2 $)_{2} \mathrm{Ph}(47)$ as an oil $(63 \mathrm{mg}, 67 \%) .{ }^{1} \mathrm{H}-$ NMR (300 MHz; $\mathrm{CDCl}_{3}$, rotamers): $\delta 7.41-7.28(\mathrm{~m}, 7 \mathrm{H}), 7.27-7.16(\mathrm{~m}, 3 \mathrm{H}), 6.66(\mathrm{~d}, J=9.7 \mathrm{~Hz}$, $1 \mathrm{H}), 6.22(\mathrm{t}, J=5.8 \mathrm{~Hz}, 0.5 \mathrm{H}), 6.01(\mathrm{t}, J=5.8 \mathrm{~Hz}, 0.5 \mathrm{H}), 5.26-5.44(\mathrm{~m}, 2 \mathrm{H}), 4.39-4.23(\mathrm{~m}, 2 \mathrm{H})$, 4.03-3.82 (m, 2H), $3.76(\mathrm{~d}, J=3.3 \mathrm{~Hz}, 1 \mathrm{H}), 3.63-3.42(\mathrm{~m}, 3 \mathrm{H}), 2.86-2.76(\mathrm{~m}, 2 \mathrm{H}), 2.40-2.06(\mathrm{~m}$, $2 H), 1.62-1.47(\mathrm{~m}, 2 \mathrm{H}), 1.39-1.27(\mathrm{~m}, 9 \mathrm{H}), 0.96-0.82(\mathrm{~m}, 6 \mathrm{H}) . \mathrm{MS}($ Method B), $m / z=542[\mathrm{M}+$ $\mathrm{H}]^{+}$.

## General Procedure B

Cbz-Orn(N-Boc)-Leu-Sta-NH(CH2) $\mathbf{2}_{2} \mathbf{P h}$ (48). A mixture of Boc-Leu-Sta-NH(CH2)2 $\mathbf{P h}$ (29) (37 $\mathrm{mg}, 0.074 \mathrm{mmol}$ ) and 4 M HCl in dioxane was stirred for 1 h at $20^{\circ} \mathrm{C}$. The reaction mixture was concentrated to dryness in vacuo to obtain the crude residue as a on oil. A mixture of the crude residue, Cbz-Orn(N-Boc)-OH ( $33 \mathrm{mg}, 0.089 \mathrm{mmol}$ ), HBTU ( $40 \mathrm{mg}, 0.104 \mathrm{mmol}$ ) and DIPEA ( 93 $\mu \mathrm{L}, 0.523 \mathrm{mmol}$ ) was allowed to stir in DMF $(1 \mathrm{~mL})$ for 18 h . The reaction mixture was quenched with $10 \%$ citric acid solution ( $1 \times 10 \mathrm{~mL}$ ) and the desired product extracted into EtOAc (3 x 15 $\mathrm{mL})$. The organic layers were combined, washed with saturated $\mathrm{NaHCO}_{3}(1 \times 20 \mathrm{~mL})$ and brine (1 x 20 mL ), dried with $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo to obtain the crude residue. The
crude residue was purified using a silica chromatography gradient eluting from $100 \%$ DCM to $10 \% \mathrm{MeOH} / \mathrm{DCM}$ to obtain Cbz-Orn(N-Boc)-Leu-NH(CH2)2Ph (48) (58 mg). ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (400 $\mathrm{MHz} ; \mathrm{CDCl}_{3}$, rotamers): $\delta 7.49-7.06(\mathrm{~m}, 10 \mathrm{H}), 6.82-6.73(\mathrm{~m}, 1 \mathrm{H}), 5.99-5.91(\mathrm{~m}, 1 \mathrm{H}), 5.05(\mathrm{~s}, 2 \mathrm{H})$, 4.32-4.24 (m, 2H), 4.00-3.91 (m, 1H), 3.91-3.84 (m, 1H), 3.79-3.70 (m, 1H), 3.67-3.58 (m, 1H), 3.56-3.33 (m, 2H), $3.17(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 3.12-2.97(\mathrm{~m}, 2 \mathrm{H}), 2.92(\mathrm{~d}, J=5.3 \mathrm{~Hz}, 1 \mathrm{H}), 2.79(\mathrm{t}, J=7.3 \mathrm{~Hz}$, $2 \mathrm{H}), 2.36-2.12(\mathrm{~m}, 3 \mathrm{H}), 1.78(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 1.64-1.46(\mathrm{~m}, 5 \mathrm{H}), 1.46(\mathrm{~s}, 9 \mathrm{H}), 1.32-1.06(\mathrm{~m}, 3 \mathrm{H}), 0.98-$ $0.69(\mathrm{~m}, 12 \mathrm{H}) . \mathrm{MS}\left(\right.$ Method B), $m / z=740[\mathrm{M}+\mathrm{H}]^{+}$.

Cbz-Orn(N-Boc)-Ala-Sta-NH(CH2)2 $\mathbf{2} \mathbf{P h}$ (49). A mixture of Cbz-Orn(N-Boc)-Ala-OEt ( 80 mg , $0.172 \mathrm{mmol})$ and LiOH hydrate $(18 \mathrm{mg}, 0.430 \mathrm{mmol})$ in a mixture of water $(0.8 \mathrm{~mL})$ and THF ( 2.4 mL ) was allowed to stir for 3 h at $20^{\circ} \mathrm{C}$. The reaction was quenched with $10 \%$ citric acid ( $1 \times 10$ mL ) and the aqueous layer extracted with EtOAc (3 x 15 mL$)$. The organic layers were combined and washed with brine ( 20 mL ), dried with anhydrous $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo to obtain an oil. The oil was dissolved in DMF ( 2 mL ) and DIPEA ( $170 \mu \mathrm{~L}, 0.953 \mathrm{mmol}$ ), HBTU $(62 \mathrm{mg}, 0.163 \mathrm{mmol})$ and $\mathrm{HCl} . \mathrm{NH}_{2}-\mathrm{Sta}-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(43 \mathrm{mg}, 0.136 \mathrm{mmol})$ was added. The mixture was then stirred for 18 h at $20^{\circ} \mathrm{C}$. The reaction was quenched with $10 \%$ citric acid (10 mL ) and the mixture extracted with EtOAc ( $3 \times 15 \mathrm{~mL}$ ). The organic layers were combined, washed with saturated $\mathrm{NaHCO}_{3}(20 \mathrm{~mL})$ and brine ( 20 mL ), dried with anhydrous $\mathrm{MgSO}_{4}$ and concentrated to dryness in vacuo to obtain Cbz-Orn(N-Boc)-Ala-NH(CH2)2 $\mathrm{Ph}(49)(43 \mathrm{mg}, 45 \%)$. ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta 7.37-6.99(\mathrm{~m}, 10 \mathrm{H}), 7.02(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 6.77(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 5.93(\mathrm{~d}, J=$ $7.4 \mathrm{~Hz}, 1 \mathrm{H}), 5.06(\mathrm{~s}, 2 \mathrm{H}), 4.39-4.29(\mathrm{~m}, 2 \mathrm{H}), 3.97-3.80(\mathrm{~m}, 2 \mathrm{H}), 3.55-3.37(\mathrm{~m}, 2 \mathrm{H}), 3.17(\mathrm{~s}, 1 \mathrm{H})$, 3.06-2.87 (m, 2H), $2.80(\mathrm{t}, J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 2.34-2.23(\mathrm{~m}, 2 \mathrm{H}), 1.81-1.77(\mathrm{~m}, 1 \mathrm{H}), 1.66-1.51(\mathrm{~m}$, $5 \mathrm{H}), 1.38-1.23(\mathrm{~m}, 13 \mathrm{H}), 0.94-0.86(\mathrm{~m}, 6 \mathrm{H}) . \mathrm{MS}\left(\right.$ Method B), $m / z=698[\mathrm{M}+\mathrm{H}]^{+}$.

Cbz-Orn(N-Boc)-Abu-Sta-NH(CH2 $\mathbf{)}_{\mathbf{2}} \mathbf{P h}$ (50). General procedure B was followed using Boc-Abu-Sta-NH(CH2)2Ph(31) (53 mg, 0.113 mmol$)$ and Cbz-Orn(N-Boc)-OH (52 mg, 0.148 mmol$)$ to obtain Cbz-Orn(N-Boc)-Abu-Sta-NH(CH2)2Ph (50) (12 mg, 14\%). ${ }^{1} \mathrm{H}-\mathrm{NMR}(300 \mathrm{MHz}$; $\left.\mathrm{CDCl}_{3}\right): \delta 7.40-7.08(\mathrm{~m}, 10 \mathrm{H}), 6.69(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 6.56(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 5.87-5.79(\mathrm{~m}, 1 \mathrm{H}), 5.10(\mathrm{~s}, 2 \mathrm{H})$, $4.94(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 4.32(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 4.22(\mathrm{~m}, 1 \mathrm{H}), 4.01-3.93(\mathrm{~m}, 1 \mathrm{H}), 3.93-3.82(\mathrm{~m}, 2 \mathrm{H}), 3.61-3.39(\mathrm{~m}$, $2 \mathrm{H}), 3.24-3.05(\mathrm{~m}, 3 \mathrm{H}), 2.81(\mathrm{t}, J=7.3 \mathrm{~Hz}, 2 \mathrm{H}), 2.39-2.15(\mathrm{~m}, 2 \mathrm{H}), 1.89-1.10(\mathrm{~m}, 18 \mathrm{H}), 1.01-0.70$ $(\mathrm{m}, 9 \mathrm{H})$. MS (Method B), $m / z=712[\mathrm{M}+\mathrm{H}]^{+}$.

Cbz-Orn(N-Boc)-Nva-Sta-NH(CH2)2 $\mathbf{2}_{2} \mathbf{P h}$ (51). General procedure B was followed using Boc-Nva-Sta-NH(CH2) $)_{2} \mathrm{Ph}(\mathbf{3 2})(57 \mathrm{mg}, 0.120 \mathrm{mmol})$ and Cbz-Orn(N-Boc)-OH (43 mg, 0.118 mmol$)$ to obtain Cbz-Orn(N-Boc)-Nva-Sta-NH(CH2)2 $\mathrm{Ph}(\mathbf{5 1})$ as a solid ( $47 \mathrm{mg}, 54 \%$ ). ${ }^{1} \mathrm{H}-\mathrm{NMR}$ (300 $\mathrm{MHz} ; \mathrm{CDCl}_{3}$, rotamers): $\delta 7.36-7.27(\mathrm{~m}, 6 \mathrm{H}), 7.26-7.15(\mathrm{~m}, 4 \mathrm{H}), 6.94-6.55(\mathrm{~m}, 2 \mathrm{H}), 5.93-5.78$ $(\mathrm{m}, 1 \mathrm{H}), 5.08(\mathrm{~s}, 2 \mathrm{H}), 5.01-4.87(\mathrm{~m}, 1 \mathrm{H}), 4.71-4.46(\mathrm{~m}, 1 \mathrm{H}), 4.39-4.19(\mathrm{~m}, 2 \mathrm{H}), 4.01-3.80(\mathrm{~m}$, 2H), 3.60-3.34 (m, 2H), 3.28-2.99 (m, 2H), 2.81 (t, $J=7.37 \mathrm{~Hz}, 2 \mathrm{H}), 2.37-2.14$ (m, 2H), 2.14$1.96(\mathrm{~m}, 3 \mathrm{H}), 1.86-1.71(\mathrm{~m}, 2 \mathrm{H}), 1.65-1.47(\mathrm{~m}, 4 \mathrm{H}), 1.43(\mathrm{~s}, 9 \mathrm{H}), 1.40-1.26(\mathrm{~m}, 3 \mathrm{H}), 0.96-0.82$ (m, 9H). MS (Method B), $m / z=726[\mathrm{M}+\mathrm{H}]^{+}$.

Cbz-Orn(N-Boc)-Val-Sta-NH(CH2 $\mathbf{)}_{2} \mathbf{P h}$ (52). A mixture of $\mathrm{HCl} . \mathrm{NH}_{2}-\mathrm{Val}-\mathrm{Sta}-\mathrm{NH}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{Ph}(60$ mg 0.117 mmol ), Cbz-Orn(N-Boc)-OH (33 mg, 0.089 mmol ), HBTU ( $40 \mathrm{mg}, 0.104 \mathrm{mmol}$ ) and DIPEA $(202 \mu \mathrm{~L})$ in DMF ( 1 mL ) was allowed to stir for 18 h at $20^{\circ} \mathrm{C}$. The reaction mixture was quenched with $10 \%$ citric acid solution $(1 \times 10 \mathrm{~mL})$ and the desired product extracted into EtOAc ( $3 \times 15 \mathrm{~mL}$ ). The organic layers were combined, washed with saturated $\mathrm{NaHCO}_{3}(1 \times 20 \mathrm{~mL})$ and brine ( $1 \times 20 \mathrm{~mL}$ ), dried with $\mathrm{MgSO}_{4}$ and concentrated in vacuo. The crude material was purified using a silica chromatography gradient eluting from $100 \% \mathrm{DCM}$ to $10 \% \mathrm{MeOH} / \mathrm{DCM}$ to obtain

Cbz-Orn(N-Boc)-Val-NH(CH2)2 $\mathrm{Ph}\left(\mathbf{5 2 )}\right.$ ( $66 \mathrm{mg}, 62 \%$ ). ${ }^{1} \mathrm{H}$ NMR data was identical to that previously described.[39] MS (Method A), $m / z=726[\mathrm{M}+\mathrm{H}]^{+}$.

## Structural Biology Experimental

Protein expression and purification. P. vivax PMV (residues R35-R476), bearing an N-terminal gp67 signal peptide and a fusion tag comprising a FLAG tag, SUMO domain and tobacco etch virus (TEV) protease-cleavage site, was expressed in SF21 insect cells. Recombinant protein was purified initially from cell supernatant with anti-FLAG M2-agarose. Pooled fractions were
concentrated, and the N -terminal fusion tag was removed with TEV protease (1:25 (v/v), 5 h at room temperature, then overnight at $4^{\circ} \mathrm{C}$ ). Gel-filtration chromatography (Superdex 75) in 20 mM HEPES, $\mathrm{pH} 7.2,100 \mathrm{mM} \mathrm{NaCl}$, and 0.2 mM DTT resulted in pure and stable protein that was concentrated for crystallization.

Structure determination. $P$. vivax PMV ( $11 \mathrm{mg} / \mathrm{ml}$ ) was co-crystallized with 27 (8 molar excess) in 0.2 M ammonium sulfate, $25 \%(\mathrm{w} / \mathrm{v})$ polyethylene glycol 3350 , and 0.1 M bis-tris chloride, pH 5.5, at the CSIRO Collaborative Crystallization Centre. Crystals were frozen in well solution supplemented with $20 \%$ ethylene glycol. Data were collected at the Australian Synchrotron MX2 beamline at 100 K using the Australian Cancer Research Fund Eiger 16M detector. Data were processed with XDS [45, 46] Pointless [45] and Aimless [47] and the structure solved by molecular replacement with Phaser [48] using the PMV chain A protein component only from PDB 4ZL4 [37]. Further rounds of building and refinement with Coot [49] and Phenix [50], incorporating simulated annealing, yielded the final model. Restraints and co-ordinates for $\mathbf{2 7}$ were generated using the Grade server [51]. GlcNAc moieties were built using Coot into density for glycosylation (derived from insect cell expression).

Molecular modelling experimental. CLC Drug Discovery Workbench software (version 2.4.1) was used to minimize each $\mathrm{P}_{2}$ analogue using the previously published $P$. vivax plasmepsin V crystal structure (PDB accession number 4ZL4) [37]. A $13 \AA$ radius binding site, centralized to binding region of WEHI-842 to plasmepsin V, was setup for minimalization of the input ligand. The water molecule present in the $\mathrm{P}_{2}$ pocket of the X-ray crystal structure was retained for docking purposes. The input ligand was built into the program using the ligand designer and WEHI-842 as a template. To minimalize the binding conformation of the input ligand, CLC Drug Discovery Workbench uses a standard mode to determine the favorable binding poses, which detects various
flexible ligand conformations while holding protein as rigid structure during docking. The default number of iterations was set at 500. The ligand binding interactions of the resulting minimization were observed using the CLC Drug Discovery visualization tool and a score calculated. The docking data was then exported into PyMOL software for the visualization and output of the image seen in Figures S1-S4. The docking score used in the Drug Discovery Workbench is the PLANTSplp [52].

## Biology Experimental

Plasmepsin V fluorogenic PEXEL cleavage assays. Recombinant $P$. vivax plasmepsin V and PEXEL cleavage assays were performed as described previously [37]. Briefly, P. vivax plasmepsin V was recombinantly expressed and purified from High Five insect cells using anti-FLAG M2agarose followed by Gel-filtration chromatography (Superdex 75). Reactions included a fluorescent peptide of nine amino acids containing the PEXEL (RTLAQ) sequence from KAHRP [29]. The KAHRP PEXEL peptide substrate DABCYL-RNKRTLAQKQ-E-EDANS was obtained commercially and used at a final assay concentration of $12 \mu \mathrm{M}$ (the Km of the substrate). The endpoint for all assays was set within the linear range of activity (approximately 1 h ). Tween- 20 was used at $0.005 \%$ final assay concentration. The final assay buffer concentration was as follows: 25 mM Tris HCl and 25 mM MES, pH 6.4. The final assay volume was $20 \mu \mathrm{~L}$ which consisted of 2.5 ng per well of recombinant $P$. vivax plasmepsin V. A ten-point 1-in-3 serial dilution of compounds was generated using DMSO as a vehicle (final assay concentration of 1\%). Assay reactions were incubated for 120 min at $37^{\circ} \mathrm{C}$ and read using a fluorescence plate reader (ex, 340 nm ; em, 495 $\mathrm{nm})$. $\mathrm{IC}_{50}$ values were determined using a nonlinear regression four-parameter fit analysis, using GraphPad Prism software, where two of the parameters were constrained to 0 and $100 \%$.

Parasite PEXEL processing assay, immunoblot, and densitometry. P. falciparum 3D7 were cultured in human $\mathrm{O}^{+}$erythrocytes at $4 \%$ hematocrit in RPMI 1640 medium supplemented with 25 mM HEPES, $\mathrm{pH} 7.4,0.2 \%$ sodium bicarbonate, and $0.5 \%$ Albumax II (Invitrogen) in culture gas $\left(5 \% \mathrm{CO}_{2}, 5 \% \mathrm{O}_{2}, 90 \% \mathrm{~N}\right)$ at $37^{\circ} \mathrm{C}$. P. falciparum 3D7 expressing PfEMP3-GFP were as generated previously [29] and treated with compounds as described previously [35]. Briefly, 24-34 h old trophozoites were purified from uninfected erythrocytes by passing the culture through a Vario Macs magnet column (Miltenyi Biotech) and cells treated with inhibitor for 3 h at $37^{\circ} \mathrm{C}$ in culture gas. Parasites were treated with $0.1 \%$ saponin to liberate contaminating hemoglobin and pellets solubilized in $4 \times$ Laemmli sample buffer before protein separation via SDS-PAGE. Proteins were transferred to nitrocellulose, blocked in $10 \%$ skim milk/PBS-T ( $0.05 \%$ ) and probed with mouse anti-GFP (Roche; 1:1000 in 1\% skim milk/PBS-T) or rabbit anti-HSP70 (Roche; 1:2000 in 1\% skim milk/PBS-T) antibodies followed by horseradish peroxidaseconjugated secondary antibodies (goat $\alpha$-mouse; Silenius; 1:1000 in $1 \%$ skim milk/PBS-T) and visualized using enhanced chemiluminescence (GE Amersham). Blots were exposed within the linear range using film or the ChemiDoc ${ }^{\text {TM }}$ Touch system (Bio-Rad), imaged or scanned and then quantified in Image Lab (Bio-Rad).

Parasite viability assay. Parasite viability assays were performed as described by Gamo et al [53]. Briefly, P.falciparum 3D7 parasites were cultured according to the procedure described by Jensen et al. [54] in RPMI-HEPES media supplemented with L-glutamine and Albumax II. Early ringstage $P$. falciparum 3D7 parasites were obtained by sorbitol synchronization and incubated with compounds solubilized in DMSO (not greater than $0.02 \%$ final to limit toxicity) in ten-point titrations. Parasitemia was determined at 72 h using a lactate dehydrogenase (LDH) readout as a percentage relative to the DMSO vehicle control. Values were plotted using a 4-parameter log
dose, non-linear regression analysis, with sigmoidal dose response (variable slope) curve fit in GraphPad Prism (ver 6.05) to generate drug curves and $\mathrm{EC}_{50}$ values.

HepG2 cell growth inhibition assay. The cell growth inhibition assays were performed as described by Gilson et al [44]. Briefly, HepG2 cells were cultured in Dulbecco's Modified Eagles Medium (DME) supplemented with $10 \%$ fetal calf serum (FCS) in a humidified incubator at $37^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$. Cells $\left(1 \times 10^{4}\right)$ were seeded in 384 well assay plates and incubated with compounds (10-point titration) for 48 hr . Cytotoxicity was determined using Cell Titer Glo. Percent viability was normalized to DMSO controls ( $100 \%$ viability) and $10 \mu \mathrm{M}$ bortezomib ( $0 \%$ viability). The $\mathrm{EC}_{50}$ was calculated using a four-parameter logistic nonlinear regression model.

## ASSOCIATED CONTENT

Supporting Information. Chemistry and biology experimental; compound dose response data; molecular modeling and X-ray data. The Supporting Information is available free of charge on the ACS Publications website.

Accession Code. PDB codes for the X-ray crystal structures described in this study have been deposited in the PDB under the accession code 6C4G.

## ACKNOWLEDGMENTS

This work was funded by the National Health and Medical Research Council of Australia (Development Grant 1113712 to B.E.S. Project Grant 1092789 and Program Grant 1092789 to A.F.C.), a CASS Foundation Science and Medicine Grant SM/15/6430 to J.A.B., the Australian

Cancer Research Foundation, the Victorian State Government Operational Infrastructure Support and Australian Government NHMRC IRIISS. A.F.C. is a Howard Hughes International Scholar. P.E.C and J.A.B are NHMRC Research Fellows (1079700 and 1123727, respectively). X-ray diffraction data was collected on the MX2 beamline at the Australian Synchrotron and made use of the ACRF Detector.

## ABBREVIATIONS

Abu - aminobutyric acid; Cav - canavanine; CyHexGly - cyclohexylglycine; CyPenGly cyclopentylglycine; EtNva - beta-ethyl-norvaline; GFP - green fluorescent protein; HBTU - O-(benzotriazol-1-yl)- $N, N, N^{\prime}, N^{\prime}$-tetramethyluronium hexafluorophosphate; $\beta$-hydroxy-Val $-\beta$ -hydroxy-valine; 2-indanylGly - 2-indanyl glycine; KAHRP - knob associated histidine rich protein; LDH - lactate dehydrogenase; $\beta$-methyl-Phe - $(2 S, 3 S)$ erythro-L- $\beta$-methyl-phenylalanine; Nva - norvaline; Orn - ornithine; PfEMP3 - P. falciparum erythrocyte membrane protein 3; PMV - plasmepsin V; PEXEL - Plasmodium export element; Pf - Plasmodium falciparum; $\beta$-phenylPhe - 3,3-diphenyl alanine; threo- $\beta$-phenyl-Ser - D,L-threo- $\beta$-phenyl serine; Pv - Plasmodium vivax; Sta - (3S,4S)-4-amino-3-hydroxy-6-methylheptanoic acid; tBuGly - tert-butyl glycine; TFA - trifluoroacetic acid.
