23

24 Receptor interacting protein kinase 1 (RIPK1) promotes cell survival because mice  
25 lacking RIPK1 die perinatally, exhibiting aberrant caspase-8-dependent apoptosis  
26 and mixed lineage kinase-like (MLKL)-dependent necroptosis<sup>1-3</sup>. However, mice  
27 expressing catalytically inactive RIPK1 are viable<sup>2,4,5</sup>, so an ill-defined pro-survival  
28 function for the RIPK1 scaffold has been proposed. Here we show that the RIP  
29 homotypic interaction motif (RHIM) in RIPK1 prevents the RHIM-containing  
30 adaptor protein ZBP1 (Z-DNA binding protein 1; also called DAI) from activating  
31 RIPK3 upstream of MLKL. *Ripk1<sup>RHIM/RHIM</sup>* mice expressing mutant RIPK1 with  
32 critical RHIM residues IQIG mutated to AAAA died around birth and exhibited  
33 RIPK3 autophosphorylation on Thr231 and Ser232, which is a hallmark of  
34 necroptosis<sup>6</sup>. Blocking necroptosis with catalytically inactive RIPK3 D161N, RHIM  
35 mutant RIPK3, RIPK3 deficiency, or MLKL deficiency prevented lethality in  
36 *Ripk1<sup>RHIM/RHIM</sup>* mice. Loss of ZBP1, which engages RIPK3 in response to certain  
37 viruses<sup>7,8</sup> but has no known role during development, also prevented perinatal  
38 lethality in *Ripk1<sup>RHIM/RHIM</sup>* mice. Consistent with the RHIM of RIPK1 functioning as  
39 a brake that prevents ZBP1 from engaging the RIPK3 RHIM, ZBP1 interacted with  
40 RIPK3 in *Ripk1<sup>RHIM/RHIM</sup> Mlkl<sup>-/-</sup>* macrophages, but not in wild-type, *Mlkl<sup>-/-</sup>* or  
41 *Ripk1<sup>RHIM/RHIM</sup> Ripk3<sup>RHIM/RHIM</sup>* macrophages. Collectively, these findings indicate that  
42 the RHIM of RIPK1 is critical for preventing ZBP1/RIPK3/MLKL-dependent  
43 necroptosis during development.

44 Studies of RIPK1 deficiency show that RIPK1 suppresses RIPK3/MLKL-dependent  
45 necroptosis in some cell types, and FADD/caspase-8-dependent apoptosis in others<sup>1-3,9-12</sup>.  
46 However, mutation of critical catalytic residues in RIPK1, or inhibition of RIPK1  
47 enzymatic activity with the small molecule necrostatin-1, does not promote cell death  
48<sup>2,4,5,11,12</sup>. Therefore, RIPK1 is hypothesized to form a pro-survival scaffold that is  
49 independent of its kinase activity. In addition to its kinase domain, RIPK1 has RHIM and  
50 death domain (DD) protein interaction motifs<sup>13</sup> (Fig. 1a). The DD mediates recruitment  
51 of RIPK1 to death receptors such as tumor necrosis factor receptor 1 (TNFR1) and to  
52 adaptor proteins such as Fas-associated via death domain (FADD), whereas the RHIM  
53 mediates interactions with RIPK3<sup>13</sup>. To determine if the RHIM of RIPK1 is an essential  
54 part of the RIPK1 pro-survival scaffold, we generated *Ripk1*<sup>RHIM/RHIM</sup> mice with RHIM  
55 core residues IQIG<sup>14</sup> mutated to AAAA (Fig. 1a).

56

57 *Ripk1*<sup>RHIM/RHIM</sup> mice died around birth (Fig. 1b) with histologic lesions in the skin being  
58 the most striking and consistent phenotype (Fig. 1c). At embryonic day 18.5 (E18.5), the  
59 epidermis was hyperplastic and the underlying dermis was expanded by edema and  
60 infiltrated with leukocytes. Similar abnormalities in *Ripk1*<sup>-/-</sup> embryos require RIPK3 and  
61 MLKL-dependent necroptosis<sup>1</sup>. Of note, *Ripk1*<sup>RHIM/RHIM</sup> embryos lacked the caspase-8-  
62 dependent intestinal lesions seen in *Ripk1*<sup>-/-</sup> embryos<sup>1</sup> (Extended data fig. 1a). These data  
63 suggest that mutation of the RIPK1 RHIM primarily unleashes the RIPK3-MLKL  
64 necroptosis pathway (Extended data fig. 1b).

65

66 RIPK3 autophosphorylation on Thr231 and Ser232 is a hallmark of necroptosis <sup>6</sup>. A  
67 phospho-specific RIPK3 antibody recognizing these sites (Extended data fig. 1, c and d)  
68 stained many cells in the skin and thymus of *Ripk1<sup>RHIM/RHIM</sup>* embryos, but rare cells  
69 throughout multiple tissues including the bladder, liver, heart and intestine were also  
70 positive (Fig. 1c and Extended data fig. 1e). Importantly, staining was absent in wild-  
71 type (WT) embryos. RIPK3 autophosphorylation in the *Ripk1<sup>RHIM/RHIM</sup>* skin coincided  
72 with increased cell death based on TUNEL staining, which marks dying cells with DNA  
73 damage (Extended data fig. 1f), and cleaved caspase-3 staining, which marks apoptotic  
74 cells (Fig. 1c). Increased cell death was less evident in the *Ripk1<sup>RHIM/RHIM</sup>* thymus  
75 (Extended data fig. 1f), perhaps because MLKL was limiting. Thymocytes expressed  
76 considerably less MLKL than necroptosis-competent macrophages (Extended data fig.  
77 1g).

78  
79 Lethality and the skin lesions in *Ripk1<sup>RHIM/RHIM</sup>* mice were prevented by either RIPK3 or  
80 MLKL deficiency, suggesting these defects stemmed from aberrant necroptosis (Fig. 1c-f  
81 and Extended data fig. 2a-d). Although RIPK3 has been linked to apoptosis induction in  
82 some contexts <sup>13</sup>, MLKL has not. Therefore, increased apoptosis in the *Ripk1<sup>RHIM/RHIM</sup>*  
83 dermis may have been a secondary consequence. *Ripk1<sup>RHIM/RHIM</sup> Ripk3<sup>+/-</sup>* mice were also  
84 viable and fertile, although 4 out of 7 mice developed severe dermatitis around the neck  
85 and ears after 6-9 months (Extended data fig. 2d). Sensitivity to *Ripk3* gene dosage was  
86 not unexpected because halving the *Ripk3* gene dosage also averts perinatal lethality in  
87 *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup>* mice <sup>2</sup>. *Ripk1<sup>RHIM/RHIM</sup>* mice expressing RIPK3 with RHIM residues  
88 VQIG mutated to AAAA (Extended data fig. 3a) or catalytically inactive RIPK3 D161N <sup>4</sup>

89 also survived beyond weaning, were fertile, and had no overt defects, albeit the eldest  
90 mice analyzed were only aged 3-6 months (Extended data fig. 3b-d). These data provide  
91 further support for necroptosis driving the lesions in *Ripk1<sup>RHIM/RHIM</sup>* mice because both the  
92 RHIM and kinase activity of RIPK3 are critical for necroptotic signaling (Extended data  
93 fig. 3e-h) <sup>15-17</sup>.

94

95 RIPK1 deficiency compromises signaling by TNF in some cell types <sup>9,18</sup> so we compared  
96 WT, *Ripk1<sup>-/-</sup>*, and *Ripk1<sup>RHIM/RHIM</sup>* primary mouse embryo fibroblasts (MEFs) after TNF  
97 treatment. Phosphorylation and degradation of I $\kappa$ B $\alpha$ , and phosphorylation of p38 and  
98 JNK were impaired in *Ripk1<sup>-/-</sup>* MEFs (Extended data fig. 4a) as reported <sup>8</sup>, but occurred  
99 normally in *Ripk1<sup>RHIM/RHIM</sup>* MEFs (Extended data fig. 4b). *Ripk1<sup>RHIM/RHIM</sup>* MEFs treated  
100 with TNF also maintained normal levels of FLIP (FLICE-inhibitory protein), the adaptor  
101 protein TRAF2 (TNF receptor associated factor 2), and the ubiquitin ligase cIAP1  
102 (cellular inhibitor of apoptosis protein 1), whereas these proteins were lost from *Ripk1<sup>-/-</sup>*  
103 MEFs (Extended data fig. 4c). Therefore, these RIPK1-dependent signaling events  
104 triggered by TNF in MEFs do not require the RIPK1 RHIM.

105

106 Next we examined necroptosis signaling in primary *Ripk1<sup>RHIM/RHIM</sup>* MEFs treated with  
107 TNF plus the pan-caspase inhibitor Z-VAD-FMK (hereafter abbreviated TZ). Similar to  
108 WT macrophages (Extended data fig. 3g and 4d), WT or *Ripk1<sup>RHIM/RHIM</sup>* MEFs exhibited  
109 RIPK1 phosphorylation on Ser166 after TZ treatment (Fig. 2a). We believe this  
110 modification represents RIPK1 autophosphorylation because it was absent when cells  
111 expressed catalytically inactive RIPK1 D138N. Interestingly, RIPK1 Ser166

112 phosphorylation was detected as early as 5 min after treatment with TNF or TZ (Fig. 2b),  
113 indicating that it is not a necroptosis-specific modification. Analysis of the TNFR1-  
114 associated signaling complex induced by TZ (Fig. 2c) indicated that WT, catalytically  
115 inactive, or RHIM mutant RIPK1 were incorporated into the complex and modified in a  
116 manner consistent with their being ubiquitylated<sup>19</sup>. However, only WT and RHIM  
117 mutant RIPK1 were also phosphorylated on Ser166. Ubiquitylation of RIPK1 is thought  
118 to contribute to TAK1 (Transforming growth factor  $\beta$ -activated kinase 1) and IKK  
119 activation<sup>20-24</sup>, so our data implying that RIPK1 autophosphorylation is dispensable for  
120 RIPK1 ubiquitylation fits with TNF activating IKK- and TAK1-dependent signaling  
121 pathways normally in *Ripk1*<sup>D138N/D138N</sup> cells<sup>4</sup> (Extended data fig. 5b).

122

123 We explored whether TNF-induced phosphorylation of RIPK1 Ser166 required RIPK1  
124 ubiquitylation by pretreating WT MEFs with the IAP (inhibitor of apoptosis protein)  
125 antagonist BV6 (Extended data fig. 5a) or by analyzing *Tradd*<sup>-/-</sup> macrophages (Extended  
126 data fig. 5b). MEFs treated with BV6 lacked detectable cIAP1, consistent with BV6  
127 inducing proteasomal degradation of the ubiquitin ligases cIAP1 and cIAP2<sup>25</sup>. In  
128 addition, RIPK1 associated with TNFR1 no longer migrated as a high molecular weight  
129 smear, consistent with it being poorly ubiquitylated (Extended data fig. 5a). However,  
130 RIPK1 phosphorylated on Ser166 was still detected, implying that RIPK1  
131 autophosphorylation does not require RIPK1 ubiquitylation. Similar results were  
132 obtained using *Tradd*<sup>-/-</sup> macrophages having reduced RIPK1 ubiquitylation in the TNFR1  
133 signaling complex (Extended data fig. 5b). Collectively, our data suggest that RIPK1

134 associated with TNFR1 undergoes ubiquitylation and autophosphorylation with one  
135 modification not requiring the other.

136

137 TZ caused RIPK1 to interact with RIPK3 in WT MEFs, whereas TNF or Z-VAD-FMK  
138 alone did not (Extended data fig. 5c). Consistent with previous studies<sup>15,16</sup>, this  
139 interaction required both the RHIM and kinase activity of RIPK1 (Fig. 2a). RIPK1  
140 interacting with RIPK3 promotes RIPK3 oligomerization and autophosphorylation<sup>26</sup>.  
141 Therefore, as expected, TZ induced RIPK3 autophosphorylation in WT MEFs, but not in  
142 *Ripk1<sup>D138N/D138N</sup>* MEFs (Fig. 2a). RIPK3 was not autophosphorylated in WT MEFs treated  
143 with TNF or Z-VAD-FMK individually (Fig. 2d). Strikingly, both *Ripk1<sup>RHIM/RHIM</sup>* and  
144 *Ripk1<sup>-/-</sup>* MEFs exhibited RIPK3 autophosphorylation in medium alone (Fig. 2a and  
145 Extended data fig. 5d). These data indicate that the RHIM of RIPK1 suppresses RIPK3  
146 activation in primary MEFs as well as in the skin and thymus of the developing mouse.  
147 RIPK3 autophosphorylation in the *Ripk1<sup>RHIM/RHIM</sup>* or *Ripk1<sup>-/-</sup>* MEFs did not induce  
148 significant cell death (Extended data fig. 5e), although it should be noted that WT MEFs  
149 were also considerably less sensitive to TZ than macrophages (Extended data fig. 3e) or  
150 immortalized MEFs<sup>4</sup>. Primary MEFs, like thymocytes, expressed less MLKL than  
151 macrophages (Extended fig. 1g) and this may contribute to their relative insensitivity to  
152 RIPK3 activation.

153

154 How might the RIPK1 RHIM suppress RIPK3 activation when interactions between  
155 RIPK1 and RIPK3 were only detected after TZ treatment (Fig. 2 and Extended data fig.  
156 5c)? Furthermore, does an upstream stimulus drive RIPK3 activation in *Ripk1<sup>-/-</sup>* or

157 *Ripk1<sup>RHIM/RHIM</sup>* cells, or does RIPK3 above a threshold level activate spontaneously? Two  
158 other RHIM-containing proteins besides RIPK1 and RIPK3 are ZBP1 and TRIF.  
159 Therefore, we tested if loss of both ZBP1 and TRIF substituted for RIPK3 deficiency and  
160 rescued lethality in *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup>* mice<sup>1-3</sup>. After intercrossing *Ripk1<sup>+/-</sup> Casp8<sup>+/-</sup> Zbp1<sup>-/-</sup>*  
161 *Trif<sup>-/-</sup>* mice, we obtained viable *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* mice with a median survival  
162 of 17 weeks, whereas *Ripk1<sup>-/-</sup> Casp8<sup>+/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* or *Ripk1<sup>-/-</sup> Casp8<sup>+/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>*  
163 littermates died within 3 weeks (Fig. 3, a and b). With the exception of two mice with  
164 severe malocclusion, all weaned *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* mice were euthanized due  
165 to lymphadenopathy from the accumulation of CD3<sup>+</sup> B220<sup>+</sup> T cells (Fig. 3, c and d), a  
166 known consequence of caspase-8 deficiency<sup>27</sup>. Lymphadenopathy was accompanied by  
167 significantly elevated serum IL-17A and CCL4/MIP-1 $\beta$  (Extended data fig. 6a). The  
168 only other consistent phenotype revealed by histological analysis of all the major organ  
169 systems at 3-6 months of age was testicular atrophy in the *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>*  
170 males (Extended data fig. 6b).

171

172 Survival of *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* mice beyond weaning suggests that ZBP1 and/or  
173 TRIF promote RIPK3 activation when RIPK1 is absent. Consistent with this notion,  
174 E18.5 *Ripk1<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* skin had few cells containing autophosphorylated RIPK3  
175 when compared to *Ripk1<sup>-/-</sup>* skin (Fig. 3e). Epidermal hyperplasia and dermatitis were still  
176 evident in *Ripk1<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* skin, but presumably this was due to caspase-8-dependent  
177 apoptosis because neither occurred in the skin of *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup> Trif<sup>-/-</sup>* mice aged  
178 3-6 months (Extended data fig. 6c). One *Ripk1<sup>-/-</sup> Casp8<sup>-/-</sup> Zbp1<sup>-/-</sup>* mouse was obtained  
179 from limited intercrossing of *Ripk1<sup>+/-</sup> Casp8<sup>+/-</sup> Zbp1<sup>+/-</sup> Trif<sup>+/-</sup>* mice and it lacked overt

180 defects at 7 weeks of age (Extended data fig. 6d). Thus, ZBP1 potentially contributes  
181 more than TRIF to *Ripk1*<sup>-/-</sup> perinatal lethality. Consistent with this idea, ZBP1 deficiency  
182 alone rescued perinatal lethality in the *Ripk1*<sup>RHIM/RHIM</sup> mice, whereas TRIF deficiency did  
183 not (Fig. 4a-c and Extended data fig. 7a). *Ripk1*<sup>RHIM/RHIM</sup> *Zbp1*<sup>-/-</sup> mice aged 7 weeks lacked  
184 histologic skin lesions but they still exhibited some RIPK3 autophosphorylation in the  
185 dermis (Fig. 4d and Extended data fig. 7b). Therefore, it is possible that TRIF-dependent  
186 RIPK3 activation might elicit lesions in older *Ripk1*<sup>RHIM/RHIM</sup> *Zbp1*<sup>-/-</sup> mice.

187

188 We sought biochemical evidence for ZBP1 or TRIF engaging RIPK3 in *Ripk1*<sup>RHIM/RHIM</sup>  
189 macrophages, but found that *Ripk1*<sup>RHIM/RHIM</sup> fetal liver cells cultured with M-CSF yielded  
190 approximately 5-fold fewer Mac-1<sup>+</sup> F4/80<sup>+</sup> macrophages than their WT counterparts  
191 (Extended data fig. 7c). Furthermore, *Ripk1*<sup>-/-</sup> or *Ripk1*<sup>RHIM/RHIM</sup> macrophages contained  
192 abnormally low amounts of ZBP1, RIPK3 and MLKL (Extended data fig. 7d), suggesting  
193 selection for cells unable to die. To circumvent these issues, we analyzed *Ripk1*<sup>RHIM/RHIM</sup>  
194 *Mkl1*<sup>-/-</sup> bone marrow-derived macrophages. No interaction between RIPK3 and TRIF was  
195 detected, but RIPK3 did coimmunoprecipitate with ZBP1 (Fig. 4e). No RIPK3/ZBP1  
196 interaction occurred in WT, *Mkl1*<sup>-/-</sup>, or *Ripk1*<sup>RHIM/RHIM</sup> *Ripk3*<sup>RHIM/RHIM</sup> macrophages,  
197 indicating that ZBP1 engages the RIPK3 RHIM only when the RIPK1 RHIM is mutated.  
198 We explored whether RIPK1 might sequester ZBP1 in WT cells and thereby prevent it  
199 from interacting with RIPK3, but failed to detect a RIPK1/ZBP1 interaction. Therefore,  
200 how the RIPK1 RHIM suppresses the ZBP1/RIPK3 interaction remains enigmatic.

201

202 ZBP1 has two N-terminal Z-DNA binding domains in addition to its C-terminal RHIMs  
203 <sup>28</sup>, and promotes necroptosis in response to murine cytomegalovirus <sup>7</sup> or influenza <sup>8</sup>  
204 infection. However, it is unclear if ZBP1 acts as a DNA sensor during infection. ZBP1  
205 is also a type I interferon-inducible gene <sup>29</sup>. ZBP1 was more abundant in E18.5  
206 *Ripk1<sup>RHIM/RHIM</sup>* skin (Extended data fig. 7e), but this **did not** (?) coincide with a marked  
207 increase in *Ifnb* expression (Extended data fig. 7f). ZBP1 was not increased in  
208 *Ripk1<sup>RHIM/RHIM</sup> Ripk3<sup>-/-</sup>* or *Ripk1<sup>RHIM/RHIM</sup> Mkl1<sup>-/-</sup>* skin, so it is possible that *Ripk1<sup>RHIM/RHIM</sup>* skin  
209 contained more ZBP1 because of infiltrating leukocytes. Immune cells undergoing  
210 necroptosis may also have enhanced RIPK3 autophosphorylation in *Ripk1<sup>RHIM/RHIM</sup>* skin  
211 compared to *Ripk1<sup>RHIM/RHIM</sup> Mkl1<sup>-/-</sup>* skin (Fig. 1c and 4f).

212

213 In sum, our analyses have revealed an unexpected role for ZBP1 in triggering necroptosis  
214 in the perinatal period. Future studies will need to address if ZBP1 senses viral infections  
215 and/or DNA in this context, or if mutation of the RIPK1 RHIM is necessary and  
216 sufficient for ZBP1/RIPK3 interactions that induce necroptosis.

291

## 292 **Acknowledgments**

293 We thank Jose Diaz, Michael Long, Claire Allen, Martin Garcia, Alexandra Verducci and  
294 Jerome Anunciacion for animal husbandry, Robert Newman, Margaret Solon and  
295 members of the Genentech genetic analysis and histology laboratories for technical  
296 assistance, and Joyce Lai and Scott Stawicki for antibody project management.

297

## 298 **Author contributions**

299 MRG and SW generated the *Ripk1*<sup>RHIM/+</sup> and *Ripk3*<sup>RHIM/+</sup> mice, KN, AM, DLD, KEW, MS  
300 and AS designed and performed experiments, VCP and JRL characterized the RIPK1 and  
301 RIPK3 autophosphorylation sites, JDW analyzed histological data, and VMD helped with  
302 experimental design.

303

## 304 **Author information**

305 Reprints and permissions information is available at [www.nature.com/reprints](http://www.nature.com/reprints). All  
306 authors were employees or visiting scientists of Genentech. Correspondence and requests  
307 for materials should be addressed to [dixit@gene.com](mailto:dixit@gene.com) or [knewton@gene.com](mailto:knewton@gene.com).

308 **Figure Legends**

309

310 **Figure 1. Mutation of the RIPK1 RHIM causes RIPK3/MLKL-dependent lethality.**

311 (a) Organization of the *Ripk1*<sup>RHIM</sup> mutant allele. Black boxes indicate exons. DD, death  
312 domain. RHIM, RIP homotypic interaction motif.

313 (b) Numbers of offspring from *Ripk1*<sup>RHIM/+</sup> parents. Strains 1 and 2 were derived from  
314 independent ES cell clones.

315 (c) E18.5 embryo sections. Cells containing autophosphorylated RIPK3 (p-RIPK3) or  
316 cleaved caspase-3 by immunohistochemistry (IHC) stained brown. H & E, hematoxylin  
317 and eosin. Scale bars, 100  $\mu$ m. Results are representative of 3-5 embryos of each  
318 genotype.

319 (d and e) Numbers of offspring from compound heterozygote parents that survived  
320 beyond weaning at  $\sim$  21 days.

321 (f) Kaplan-Meier plot of mouse survival. Mice were either found dead (&) or euthanized  
322 because of an enlarged abdomen (#) or skin lesions (\*).

323

324 **Figure 2. The RIPK1 RHIM is dispensable for RIPK1 autophosphorylation but**  
325 **mediates interactions with RIPK3 in response to TZ.**

326 (a-d) Western blots of MEFs or immunoprecipitations (IP) performed with the indicated  
327 antibodies. T, TNF. Z, Z-VAD-FMK. p-RIPK1, phosphorylated RIPK1 Ser166. p-  
328 RIPK3, phosphorylated RIPK3 Thr231 and Ser232. Asterisks indicate non-specific  
329 bands. Results are representative of 2 (c), 4 (a and b) or 5 (d) independent experiments.

330

331 **Figure 3. Combined ZBP1 and TRIF deficiency rescues perinatal lethality in *Ripk1*<sup>-/-</sup>**  
332 ***Casp8*<sup>-/-</sup> mice.**

333 (a) Numbers of offspring of *Ripk1*<sup>+/-</sup> *Casp8*<sup>+/-</sup> *Zbp1*<sup>-/-</sup> *Trif*<sup>fl/-</sup> parents.

334 (b) Kaplan-Meier plot of mouse survival. Note that animals clipped at P3-P6 and not  
335 found at weaning were recorded as dead at 21 d, but may have died earlier.

336 (c) Spleen and lymph nodes (mesenteric, brachial, and inguinal) of male littermates aged  
337 18 weeks.

338 (d) Flow cytometric analysis of lymph node cells from female mice aged 15-17 weeks.

339 (e) E18.5 skin sections. Cells containing autophosphorylated RIPK3 (p-RIPK3) by  
340 immunohistochemistry (IHC) stained brown. Scale bar, 100 μm.

341 Results in (c-e) are representative of 3-4 mice of each genotype.

342

343 **Figure 4. ZBP1 interacts with RIPK3 to trigger necroptosis in *Ripk1*<sup>RHIM/RHIM</sup> mice.**

344 (a and b) Numbers of offspring from compound heterozygote parents that survived  
345 beyond weaning at ~ 21 days.

346 (c) Kaplan-Meier plot of mouse survival.

347 (d) Skin sections from female littermates aged 7 weeks. Cells containing  
348 autophosphorylated RIPK3 (p-RIPK3) by immunohistochemistry (IHC) stained brown.

349 Scale bar, 100 μm. Results are representative of 2 *Ripk1*<sup>RHIM/RHIM</sup> *Zbp1*<sup>-/-</sup> mice.

350 (e) Western blots of macrophages or immunoprecipitates (IP). Results are representative  
351 of 4 independent experiments.

352

353 **Methods**

354 **Mice**

355 *Ripk3*<sup>-/-</sup> 4, *Ripk3*<sup>D161N/D161N</sup> 4, *Ripk1*<sup>D138N/D138N</sup> 4, *Ripk1*<sup>-/-</sup> 4, *Casp8*<sup>-/-</sup> 4, *Tradd*<sup>-/-</sup> 22, *Mkl1*<sup>-/-</sup> 30,  
356 *Zbp1*<sup>-/-</sup> 31, and *Trif*<sup>-/-</sup> 32 mice were described previously. A second *Zbp1*<sup>-/-</sup> strain generated  
357 by Taconic (Germany) using C57BL/6NTac ES cells was also crossed to *Ripk1*<sup>RHIM/RHIM</sup>  
358 mice and rescued perinatal lethality similar to the published *Zbp1*<sup>-/-</sup> strain 31 so results  
359 were pooled. The Taconic strain lacked the *Zbp1* 5' UTR and exon 1 corresponding  
360 to NCBI37/mm9 chr2:173,043,537-173,045,687. *Ripk1*<sup>RHIM/+</sup> and *Ripk3*<sup>RHIM/+</sup> mice were  
361 generated at Genentech using C57BL/6N C2 ES cells. A *FRT*-flanked neomycin  
362 selection cassette inserted upstream of *Ripk1* exon 10 at position chr13:34,029,090  
363 (GRCm38/mm10 assembly) or upstream of *Ripk3* exon 10 at position chr14:55,785,501  
364 (reverse strand) was deleted from the targeted ES cells prior to microinjection by  
365 adenoviral delivery of Flpe. *Ripk1* sequence ATT CAG ATT GGA encoding RHIM  
366 residues IQIG was replaced with the sequence GCT GCG GCT GCA. *Ripk3* sequence  
367 GTG CAG ATT GGG encoding RHIM residues VQIG was replaced with the sequence  
368 GCA GCC GCG GCT.

369

370 *Ripk1*<sup>RHIM</sup> genotyping primers 5' CCA CAT TCT TGC CAA CAC TG and 5' GCA AGT  
371 ATT GTT TGG TGG TTG amplified 299 base pair (bp) wild-type and 333 bp knock-in  
372 DNA fragments. *Ripk3*<sup>RHIM</sup> genotyping primers 5' AGC AGG CAC TAC TCT TTG  
373 AGC T and 5' CTG TGC TTG GTC ATA CTT GGC amplified 325 bp wild-type and  
374 359 bp knock-in DNA fragments. *Zbp1* genotyping primers 5' AGA CCA TTA GAA  
375 AGC ACA GAT C, 5' TGG CCT CTC CTT CAT TCC and 5' CTC CTA GGT CAG

376 TGA CTC TC amplified 145 bp wild-type and 294 bp knock-out (Taconic strain) DNA  
377 fragments.

378

379 For timed pregnancies, mice were designated E0.5 on the morning a vaginal plug was  
380 detected. When determining offspring numbers, pups were clipped between 3-6 days of  
381 age. The Genentech institutional animal care and use committee approved all protocols.

382

### 383 **Immunohistochemistry**

384 Formalin-fixed, paraffin-embedded tissue sections were stained with 5 µg/ml rabbit anti-  
385 mouse phospho-RIPK3 antibody (GEN135-35-9, Genentech) recognizing phosphorylated  
386 residues Thr231, Ser232. Immunohistochemistry was performed on the Ventana  
387 Discovery XT platform with CC1 standard antigen retrieval. The reaction was detected  
388 with the HQ amplification system using DAB as the chromogen and hematoxylin  
389 counterstain. **Josh to insert CC3 IHC and TUNEL staining methods.**

390

### 391 **Cell culture**

392 Primary MEFs isolated from E13.5 or E14.5 embryos were grown in the high glucose  
393 version of Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% heat  
394 inactivated-fetal bovine serum, 2 mM glutamine, 10 mM HEPES (pH 7.2), 1X non-  
395 essential amino acids solution, 100 U/ml penicillin, and 100 µg/ml streptomycin on tissue  
396 culture dishes pre-coated with 0.1% gelatin in PBS. Primary macrophages were  
397 differentiated from bone marrow cells in non-treated plates using the same medium  
398 supplemented with 25 ng/ml M-CSF (R&D Systems) for 5-6 d. Bone marrow-derived

399 macrophages (BMDMs) were then harvested and replated for experiments. BMDMs and  
400 MEFs were stimulated with 100 ng/ml murine TNF (Genentech), 20  $\mu$ M Z-VAD-FMK  
401 (Promega), 100 ng/ml ultra-pure LPS-EB (Invivogen), 50  $\mu$ g/ml LMW poly I-C  
402 (Invivogen), 2  $\mu$ M BV6 (Genentech), 1  $\mu$ g/ml <sup>Flag</sup>TNF (Enzo Life Sciences) or 20  $\mu$ g/ml  
403 cycloheximide (Sigma). BMDM viability was assessed after YOYO-1 (Molecular  
404 Probes) staining and live cell imaging in an Incucyte system (Essen Bioscience).  
405 Alternatively, BMDMs were harvested from non-treated plates with a cell scraper into the  
406 culture medium along with any floating dead cells, stained with 2.5  $\mu$ g/ml propidium  
407 iodide (PI; BD Biosciences), and analyzed in a FACSCanto II (BD Biosciences).

408

409 E14.5 fetal liver cells were plated overnight in high glucose DMEM supplemented with  
410 10% heat inactivated-fetal bovine serum, 2 mM glutamine, 100  $\mu$ M asparagine, 55  $\mu$ M 2-  
411 mercaptoethanol, 50 U/ml penicillin, and 50  $\mu$ g/ml streptomycin.  $2.5 \times 10^6$  viable,  
412 nucleated, non-adherent cells were then plated on a 15 cm non-treated dish in 50 ng/ml  
413 M-CSF (R&D Systems) for 7 days. Adherent cells were harvested with a cell scraper,  
414 counted, and then analyzed by flow cytometry after staining with antibodies recognizing  
415 FITC-conjugated MCA497, CI:A3-1 anti-F4/80 (Bio-Rad), PE-conjugated M1/70 anti-  
416 Mac-1 (BD Biosciences), and APC-conjugated RB6-8C5 anti-Gr-1 (BD Biosciences).  
417 Dead cells that stained with PI were excluded from analyses.

418

419 Lymph node cells were stained with FITC-conjugated 145-2C11 anti-CD3 (BD  
420 Biosciences) and APC-conjugated RA3-6B2 anti-B220 (BD Biosciences) antibodies for  
421 flow cytometric analysis. Dead cells that stained with PI were excluded from analyses.

422

423 To test the specificity of the GEN135-35-9 anti-phospho-RIPK3 antibody, 293T cells  
424 (ATCC) were transfected with N-terminal 3xFlag-tagged mouse RIPK3 variants in vector  
425 pCMV-3Tag-6 (Agilent) using lipofectamine 2000 (ThermoFisher).

426

#### 427 **Immunoprecipitation and western blotting**

428 Cells were lysed in 20 mM Tris.HCl pH 7.5, 135 mM NaCl, 1.5 mM MgCl<sub>2</sub>, 1 mM  
429 EGTA, 1% Triton X-100, 10% glycerol, phosSTOP phosphatase inhibitor (Roche), and  
430 complete protease inhibitor cocktail (Roche) (Figure 2 and Extended data fig. 1c, 3, 4a-c,  
431 5 and 7g). Insoluble material was removed by centrifugation at 14,000 rpm prior to  
432 immunoprecipitation or addition of LDS sample buffer. Alternatively, cells were lysed in  
433 10 mM Tris.HCl pH 7.5, 150 mM NaCl, 2.5 mM MgCl<sub>2</sub>, 0.5 mM CaCl<sub>2</sub>, 1% NP40,  
434 phosphatase/protease inhibitors (Roche) and DNase (~80 U/ml, Qiagen) (Extended data  
435 fig. 1d, 4d and 7f). The whole cell lysate was denatured directly in LDS sample buffer.

436

437 Immunoprecipitating antibodies recognized RIPK1 (cat#610459, BD Biosciences),  
438 RIPK3 (cat#NBP1-77299, Novus Biologicals), ZBP1 (clone Zippy-1, Adipogen), FLAG  
439 (clone M2, Sigma), or were irrelevant control IgGs (Mouse IgG2a, BD Biosciences,  
440 553454; or Rabbit IgG, Millipore, 12-370). Antibody complexes were recovered with  
441 magnetic protein A/G beads (Pierce) or magnetic FLAG beads (Sigma).

442

443 Western blot antibodies recognized RIPK3 (1G6.1.4, Genentech), phosphorylated RIPK3  
444 Thr231, Ser232 (GEN135-35-9 raised against peptide ELVDK(pT)(pS)LIRET,

445 Genentech), RIPK1 (BD Biosciences), phosphorylated RIPK1 Ser166 (GEN150-33-4  
446 raised against peptide GVASFKTW(pS)KLTKEK, Genentech), FLAG (clone M2,  
447 Sigma),  $\beta$ -actin (MP Biomedicals, mouse clone C4), FADD (1.28E12, Genentech),  
448 caspase-8 (1G12, Enzo Life Sciences), FLIP (2.21H2, Genentech), MLKL (1G12,  
449 Genentech), TRAF2 (cat#7187, Santa Cruz Biotechnology), cIAP1 (cat#ALX-803-335-  
450 C100, Enzo Life Sciences), and TRADD (GN-21-3, Genentech). The following  
451 antibodies were from Cell Signaling Technologies: p-ERK (cat#9101), ERK (cat#9102),  
452 p-JNK (cat#4668), JNK (cat#9258), p-I $\kappa$ B $\alpha$  (cat#2859), I $\kappa$ B $\alpha$  (cat#9242), p-p65/RelA  
453 (cat#3033), p65/RelA (cat#8242), p-p38 (cat#9211), and p38 (cat#8690). RIPK3  
454 antibody 1G6 was biotinylated using a Biotin-xx Microscale Protein Labeling Kit  
455 (Molecular Probes) in order to detect RIPK3 in ZBP1 immunoprecipitates.

456

#### 457 **Chemokines and cytokines**

458 E18.5 mouse skin was homogenized in ice-cold 50 mM Tris HCl pH 7.4, 150 mM NaCl,  
459 2 mM EDTA, 0.5% sodium deoxycholate, 0.1% SDS, 1% NP-40, and 1 mM DTT  
460 supplemented with complete protease inhibitor cocktail (Roche). Insoluble material was  
461 pelleted at 20,000xg and the protein concentration in the soluble fraction measured by  
462 Bio-rad Protein Assay. Skin lysates adjusted to 1 mg protein/ml or sera were analysed by  
463 Bio-Plex Pro Mouse Cytokine 23-plex (Bio-Rad).

475 **Extended Data Figure Legends**

476

477 **Extended data figure 1. Characterization of *Ripk1* mutant mice with a monoclonal**  
478 **antibody recognizing autophosphorylated RIPK3.**

479 (a) E17.5 colon sections stained with hematoxylin and eosin. Scale bar, 100  $\mu$ m. Results  
480 are representative of 3 mice of each genotype.

481 (b) Model for RIPK3 activation following mutation of the RIPK1 RHIM.

482 (c) Western blots of HEK293T cells transfected with Flag-tagged mouse RIPK3 variants,  
483 overexpression being sufficient to activate RIPK3 autophosphorylation on Thr231 and  
484 Ser232 based on mass spectrometry (data not shown). p-RIPK3, RIPK3 phosphorylated  
485 on Thr231, Ser232.

486 (d) Western blots of macrophages at 4 h after treatment. T, TNF. Z, Z-VAD-FMK.  
487 Results are representative of 5 independent experiments.

488 (e and f) E18.5 embryo sections. In (e), cells containing autophosphorylated RIPK3 are  
489 stained brown (rare positive cells are indicated by arrows). In (f), dying cells that are  
490 TUNEL-positive are black. Scale bar, 50  $\mu$ m (except the skin and thymus, which have a  
491 100  $\mu$ m scale bar). Results are representative of 3-5 mice of each genotype. Graph in (f)  
492 indicates quantification of p-RIPK3, cleaved caspase-3, and TUNEL staining in the E18.5  
493 skin and thymus.

494 (g) Western blots of WT bone marrow-derived macrophages (BMDMs), MEFs, and adult  
495 mouse thymus. Results are representative of 2 independent experiments.

496

497 **Extended data figure 2. Characterization of *Ripk1*<sup>RHIM/RHIM</sup> mice lacking RIPK3 or**  
498 **MLKL.**

499 (a) E18.5 skin cytokines and chemokines. Bars indicate the mean  $\pm$  s.e.m. n=5 embryos  
500 of each genotype. Asterisks indicate significant differences in *Ripk1*<sup>RHIM/RHIM</sup> skin  
501 compared to WT by student t-test. \* p<0.05, \*\* p<0.01, \*\*\*p<0.001.

502 (b) Body weights of mice aged 7-8 months. Each symbol represents one mouse. Lines  
503 indicate the mean.

504 (c) Serum cytokines and chemokines of mice aged 8-12 months. Bars indicate the mean  
505  $\pm$  s.e.m of 3 females and 3 males of each genotype.

506 (d) Hematoxylin and eosin stained skin sections of female mice aged 9 months. Scale  
507 bar, 100  $\mu$ m. Results are representative of 3-4 WT, *Ripk1*<sup>RHIM/RHIM</sup> *Ripk3*<sup>-/-</sup>, and  
508 *Ripk1*<sup>RHIM/RHIM</sup> *Mkl1*<sup>-/-</sup> male or female mice.

509

510 **Extended data figure 3. *Ripk1*<sup>RHIM/RHIM</sup> mice expressing catalytically inactive or**  
511 **RHIM mutant RIPK3 are viable.**

512 (a) Organization of the *Ripk3*<sup>RHIM</sup> mutant allele. Black boxes indicate exons. RHIM, RIP  
513 homotypic interaction motif.

514 (b and c) Numbers of offspring from compound heterozygote parents that survived  
515 beyond weaning at  $\sim$  21 days.

516 (d) Kaplan-Meier plot of mouse survival.

517 (e) Graph indicates the percentage of macrophages that are viable and not stained by  
518 propidium iodide (PI<sup>neg</sup>) at 16 h after treatment. T, TNF. L, LPS. P, poly I-C. Z, Z-

519 VAD-FMK. Bars are the mean  $\pm$  s.e.m. Cells from 3 mice of each genotype were  
520 analyzed.

521 (f) Representative images of macrophages stained with YOYO-1 at 16 h after the same  
522 treatments as in (e). Note that this assay does not reveal death in response to TNF, LPS  
523 or poly I-C individually. Therefore, the death quantified in (e) due to TNF, LPS or poly  
524 I-C individually is probably linked to mechanical scraping of the cells prior to flow  
525 cytometry.

526 (g and h) Western blots of macrophages. Results are representative of 2 independent  
527 experiments.

528

529 **Extended data figure 4. Comparison of *Ripk1*<sup>-/-</sup> and *Ripk1*<sup>RHIM/RHIM</sup> MEFs.**

530 (a-d) Western blots of MEFs (a-c) or macrophages (d). p- indicates an active,  
531 phosphorylated variant of the protein. Results are representative of 2 (b), 3 (a) or 5 (d)  
532 independent experiments.

533

534 **Extended data figure 5. Biochemical analyses of RIPK1 following TNF stimulation.**

535 (a-d) Western blots of MEFs (a, c and d) or macrophages (b). MEFs in (a) that received  
536 BV6 were pretreated for 2 h prior to stimulation with <sup>Flag</sup>TNF. In (d), MEFs derived from  
537 3 different embryos of each genotype were analyzed.

538 (e) Graph indicates the percentage of primary MEFs that are viable and not stained by  
539 propidium iodide (PI<sup>neg</sup>) at 25 h after treatment. T, TNF. Z, Z-VAD-FMK. C,  
540 cycloheximide. Each symbol represents cells from a different embryo. Lines indicate the  
541 mean.

542

543 **Extended data figure 6. Characterization of *Ripk1*<sup>-/-</sup> *Casp8*<sup>-/-</sup> *Trif*<sup>-/-</sup> *Zbp1*<sup>-/-</sup> mice.**

544 (a) Serum cytokines and chemokines of mice aged 4-5 weeks (upper graph) or 3-6  
545 months (lower graph). Bars indicate the mean  $\pm$  s.e.m of 3-4 mice of each genotype.

546 Asterisks indicate significantly different amounts by students t-test ( $p < 0.05$ ).

547 (b) Hematoxylin and eosin stained testes sections from mice aged 12 weeks. Scale bar,

548 100  $\mu$ m. Results are representative of two *Ripk1*<sup>-/-</sup> *Casp8*<sup>-/-</sup> *Trif*<sup>-/-</sup> *Zbp1*<sup>-/-</sup> males.

549 (c) Hematoxylin and eosin stained skin sections from female littermates aged 19 weeks.

550 Scale bar, 100  $\mu$ m. Results are representative of three *Ripk1*<sup>-/-</sup> *Casp8*<sup>-/-</sup> *Trif*<sup>-/-</sup> *Zbp1*<sup>-/-</sup> mice.

551 (d) Skin sections from male mice aged 7 weeks.

552

553 **Extended data figure 7. The effect of DAI and/or TRIF deficiency on *Ripk1*<sup>RHIM/RHIM</sup>**  
554 **mice.**

555 (a) E18.5 skin sections. Scale bar, 100  $\mu$ m. Results are representative of 3 embryos of  
556 each genotype.

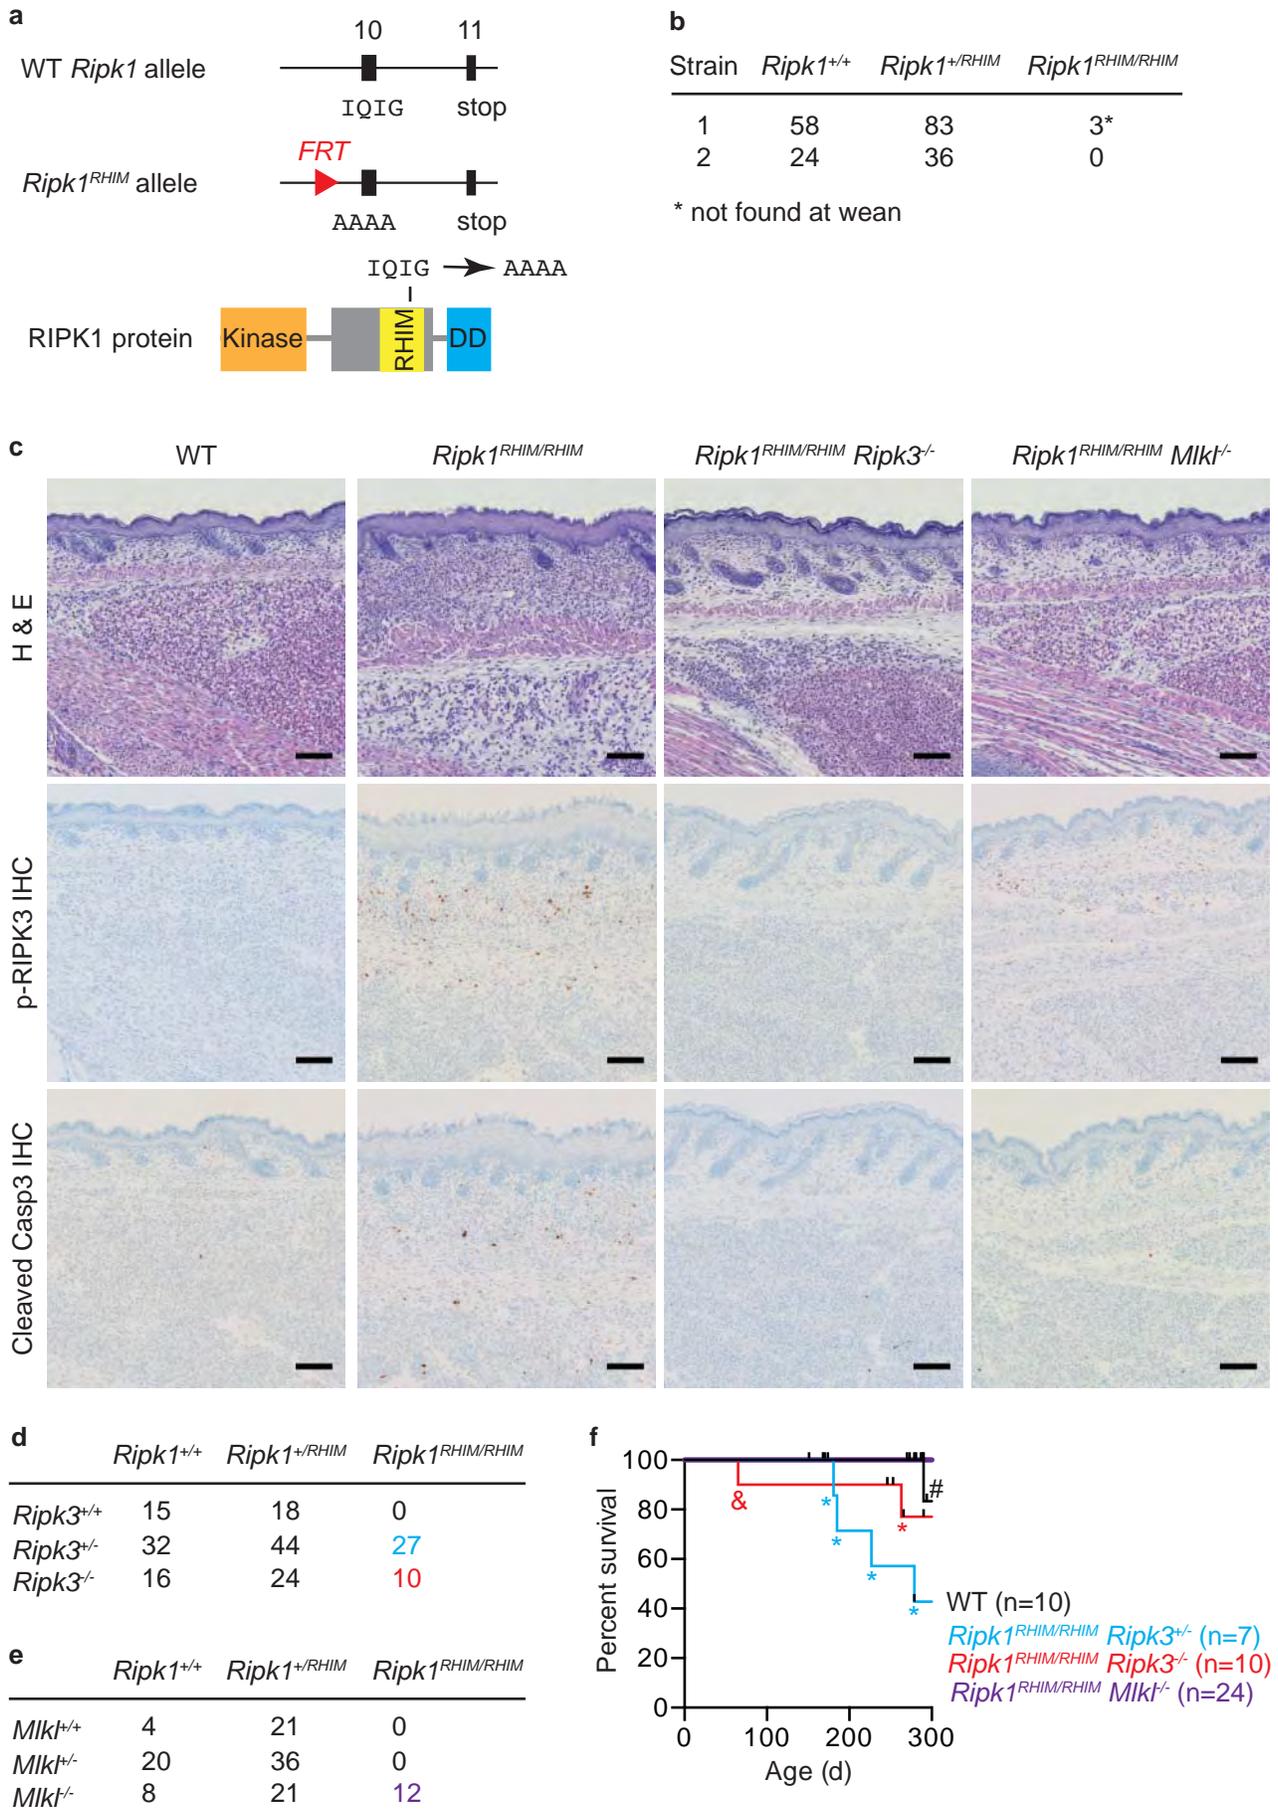

557 (b) Western blots of skin from mice aged 6-8 weeks.

558 (c) Graph indicates the number of F4/80<sup>+</sup> Mac-1<sup>+</sup> macrophages obtained after  $2.5 \times 10^6$   
559 E14.5 viable, nucleated fetal liver cells were cultured in M-CSF for 7 days. Each symbol  
560 represents cells from one embryo. Lines indicate the mean.

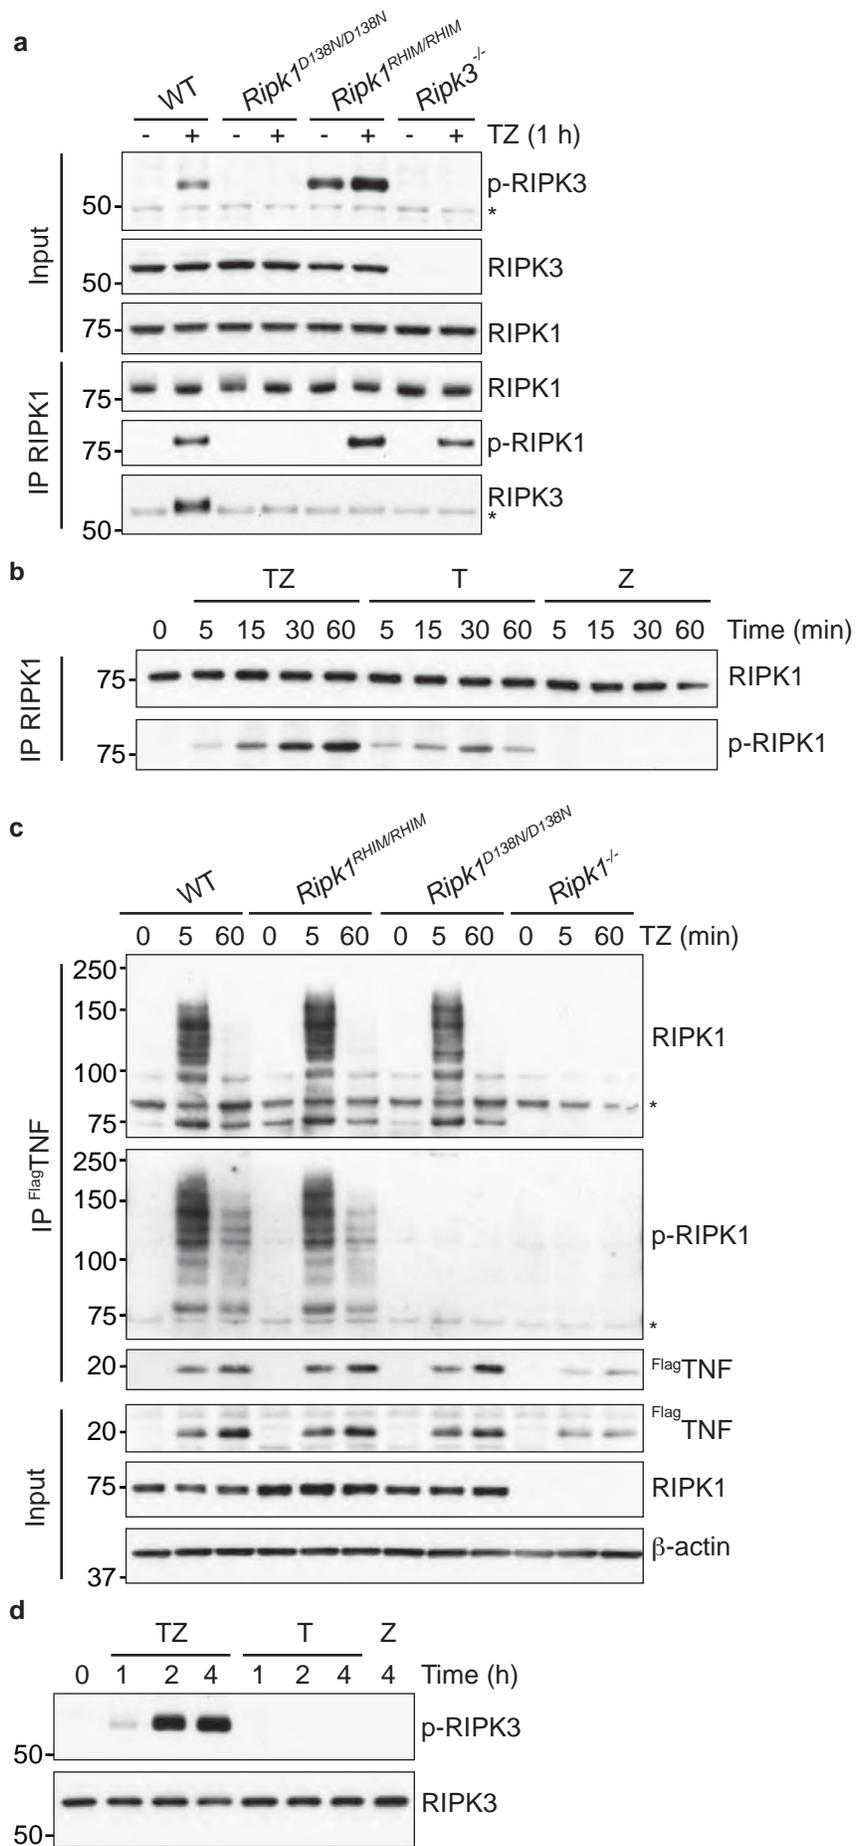

561 (d) Western blot analysis of the macrophages in (c). Cells from two embryos of each  
562 genotype were analyzed.

563 (f) Western blot analysis of E18.5 skin. Three embryos of each genotype were analyzed.

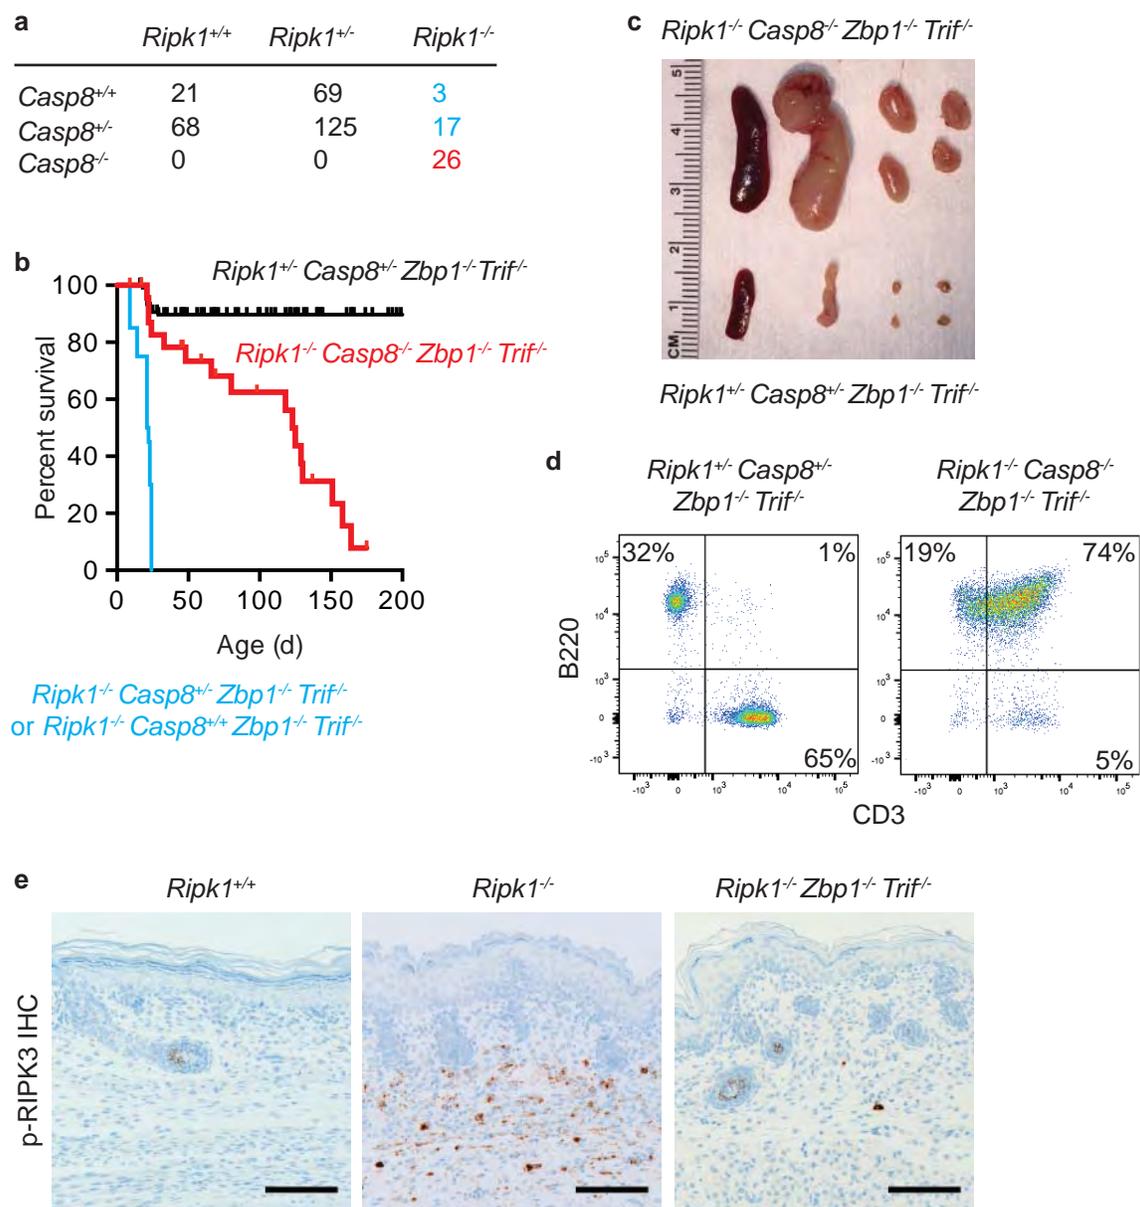

564 (g) Graph indicates *Ifnb* gene expression in E18.5 skin. Bars are the mean  $\pm$  s.e.m. n=?
